Project Overview

Time line:

- Start date: October 2001
- End date: open
- Percent complete: 50%

Budget:

- Funding FY02-05: \$800k
- FY04: \$250k
- FY05: \$250k

Barriers addressed:

- Durability
- Cost
- **Electrode performance**
- Startup time/Transient operation

Collaborations:

- Korea Advanced Institute of Science and Technology: **Professor Joong-Myeon Bae**
- Motorola
- Idaho National Laboratory

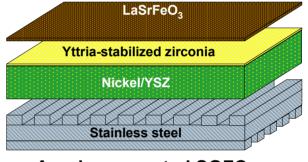

Project Objectives

- To develop a new solid oxide fuel cell (SOFC) concept for auxiliary power units and portable power applications
- Address the following SOFC issues:
 - Stack sealing
 - Startup time
 - Durability to temperature cycling
 - Materials and manufacturing cost

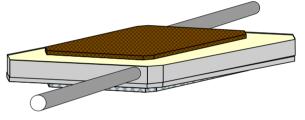

Anode-supported SOFC

Technical approach addresses SOFC issues

- Support cell on metallic bipolar plate to improve durability, cyclability, and shock-resistance
- Minimize content of expensive ceramics (anode, electrolyte, and cathode)
- Fabricate cell components using powder metallurgy techniques
- Eliminate manufacturing steps to reduce cost
- Eliminate sealing issue by developing self-sealed design

Self-Sealed Metallic Bipolar Plate Supported SOFC

Progress vs. FY05 Milestones

Complete Cost Analysis for TuffCell Stacks (2/05)

Estimated Costs:

- Materials \$69/kW
- Manufacturing (Equipment, Personnel, Operating) \$134/kW
- Total: \$203/kW
- Fabricate and test a three-cell stack (6/05)
 - 2-Cell stack was built on 12/04. Achieved 2 volts OCV in 3% H₂ bal. He.
 - Three single cell units were tested in 1/05.
 - 3-Cell stack built 3/05. Achieved 3 volts OCV in 50% H₂, 3%H₂O, bal. He
- Complete start-up time and cyclability tests (9/05)
 - Single cell stack units, cyclability tests have begun Achieved 4 cycles at 10°/min heating rates. 5

Basis of TuffCell and Anode-supported SOFC cost comparison

- Previous Excel spreadsheet was written to calculate the materials and manufacturing costs of conventional Anode-supported SOFC stacks.
- The spreadsheet was updated and modified to calculate materials and manufacturing costs of TuffCell stacks.
- 12 worksheets of calculations for each SOFC type.
- Basis:
 - Stack specifications: 5 kW, 42 V, 14x14 cm² active, 60 cells
 - Manufacturing:
 - 500,000 stacks/year
 - Conventional ceramic processing methods and equipment
 - Plant operation: 24h/day,7day/wk, 49wk/yr
 - Raw materials costs: *determined by direct contact with vendors, web- based and published prices*

TuffCell provides significant cost savings over Anode-supported SOFC

Energy Efficiency and Renewable Energy

U.S. Department of Energy, EERE Hydrogen, Fuel Cells & Infrastructure Technologies Program

Last year's stack depended on conventional sealing methods

- Edge Seal
- Gasket seals depended on flat cells
- Corner seals difficult to achieve

U.S. Department of Energy, EERE Hydrogen, Fuel Cells & Infrastructure Technologies Program

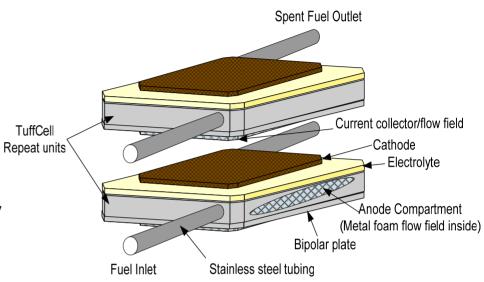

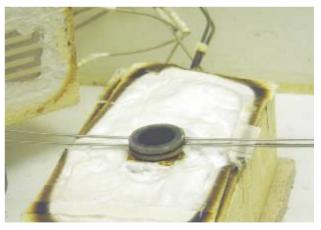

New seal concept simplifies stack building

Circular geometry

Edges of anode chamber

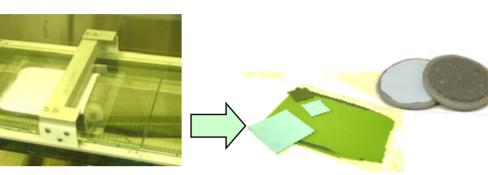

Stack test

U.S. Department of Energy, EERE Hydrogen, Fuel Cells & Infrastructure Technologies Program

TuffCell design and fabrication process address SOFC shortcomings

Tape cast cell layers (w/o cathode)

Laminate and cut tapes & foam

- Thin layers of expensive ceramics
- Brittle ceramics bonded to tough metallic layers
- Single, programmed high temperature process
- Single electrical contact plane between cells
- Self-sealed fuel chamber (NEW)

Sinter in single hightemperature process

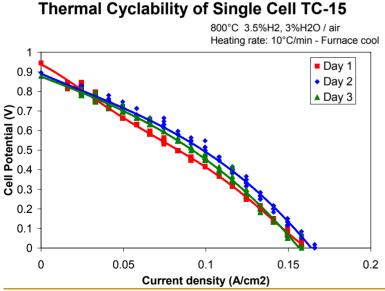

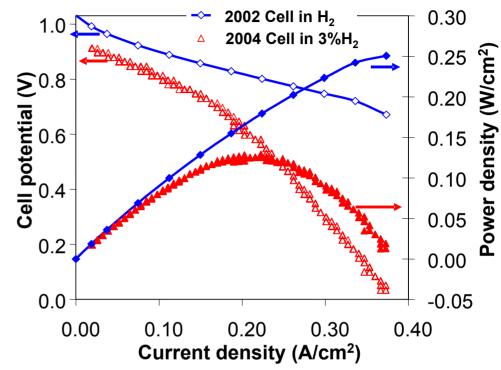

Braze gas tubes Slurry-coat cathode

New sealed design test shows comparable performance to previous TuffCell tests

- New design: 0.14 mA/cm² @ 0.76 V
- Previous test: 0.26 mA/cm² @ 0.77 V
- **Two-cell stack achieved** 2.0 volt OCV

 Thermal cyclability tests have begun with single cell stack units

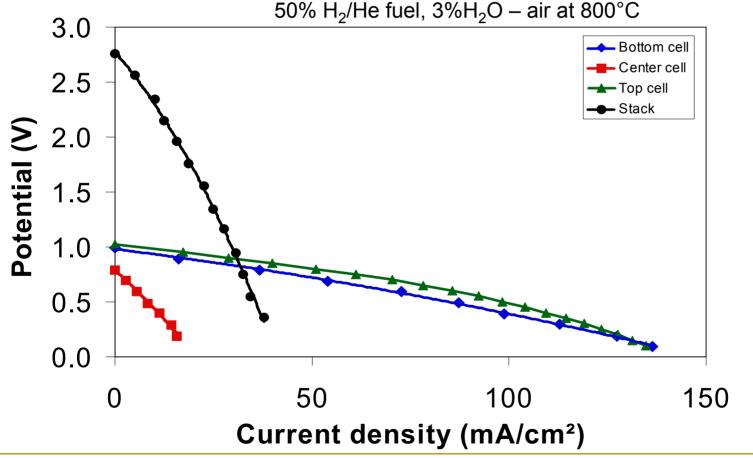

U.S. Department of Energy, EERE Hydrogen, Fuel Cells & Infrastructure Technologies Program

First 3-cell stack:

- Stack reached open circuit potential
- Stack polarization test :

Reviewers' comments from FY '04 meeting

- Comment 1: "Need successful scale-up / stack test to attract additional non-DOE investment."
 - The new seal concept has simplified stack building. Single cell and multi-cell stacks are presently being fabricated, tested & improved.
- Comment 2: "Focus on improving power density."
 - The co-firing process produces a reduced Ni anode. This makes it more difficult to control the anode microstructure to produce high power densities. As the overall sintering process is becoming finalized, more attention is being paid to optimizing the anode microstructure and performance.
- Comment 3: "This concept could revolutionize SOFC design."
 - The metal supported SOFC concept is beginning to catch on with SOFC developers.
 - The new seal concept overcomes major sealing hurdles in building SOFC stacks.

Future Plans – FY '06 and Beyond

- Improve single cell performance
- Demonstrate stack thermal cyclability with <30 min startup time
- Provide sample cells to
 - Motorola for low power cell tests
 - Idaho National Laboratory for High Temperature Steam Electrolysis
- Demonstrate long term stack/cell performance tests
- Transfer technology for scale-up and system integration

- Funding from the U.S. Department of Energy, Energy Efficiency, Renewable Energy: Hydrogen, Fuel Cells & Infrastructure Technologies Program is gratefully acknowledged
- Nancy Garland, DOE Technology Development Manager

The most significant hydrogen hazard associated with this project is:

The greatest hydrogen hazard in this project is the possibility forming a flammable (4%< % H_2 < 75%, by volume)* or an explosive (18%< % H_2 < 59%, by volume) mixture with air in a closed volume at ignition temperature (>500°C). This could happen in two instances within the project. The SOFC is sintered in hydrogen in a closed tube furnace at temperatures ranging from 800°C to 1400°C. Also, during cell or stack testing, hydrogen flows through a closed anode chamber in the TuffCell. In either case, if hydrogen is introduced into the closed chamber at the concentrations listed above without purging the air, ignition could occur.

*W. F. Baade, U. N. Parekh, and V. S. Raman, in Kirk-Othmer Encyclopedia of Chemical Technology, 2001, John Wiley & Sons, Inc., http://www.mrw.interscience.wiley.com/kirk, Accessed in 2005

Our approach to deal with this hazard is:

When hydrogen concentrations greater than 4 vol% are introduced into our system, it is first purged with nitrogen, helium, argon, or a non-flammable regen gas (<4% H_2 / He) for sufficient time to remove oxygen out of the chamber down to parts per thousand levels. The sintering furnaces are tested for purge times using a residual gas analyzer, and automatic programs were set to flow nitrogen for the required time. In the cell and stack test experiments, the cells are heated with regen gas flowing through the anode chamber and the hydrogen is introduced if the theoretical open circuit potential is achieved. Both experiments are contained within fume hoods with high exhaust rates that prevent the accumulation of hydrogen within the hood.
