## **Introduction to Hydrogen for Code Officials**

This course was developed to help code officials—

- Understand the basic properties of hydrogen and fuel cell technologies
- Be familiar with fuel cell applications
- Know where to find codes and standards applicable to hydrogen technologies

A short quiz is offered at the end of each module and a printable certificate of completion is offered at the end of the course.

## Hydrogen Basics

Although we never see it, hydrogen is everywhere in the world around us. It's the simplest element on Earth and the most abundant element in the universe.

A hydrogen atom consists of one proton and one electron. A hydrogen molecule consists of two hydrogen atoms, so hydrogen is often abbreviated as H<sub>2</sub>. Hydrogen combines easily with other elements. On Earth, it's rarely found in pure form. Instead, it is found in combinations such as water, methane, and biomass.

## Hydrogen as an Energy Carrier

Hydrogen isn't a primary energy source. Instead, it's an energy carrier (like electricity), meaning that it can store and deliver energy in an easily usable form.

Hydrogen's volumetric energy content is relatively low. Compared to natural gas, hydrogen—when burned—releases only one-third the energy per cubic foot of gas. Because of its low molecular weight, however, hydrogen has the highest energy content per pound of any fuel.

## Hydrogen Characteristics

At standard temperature and pressure, hydrogen is a gas that human senses can't detect.

Hydrogen gas is:

- Odorless
- Tasteless
- Nontoxic
- Colorless
- Stable
- Noncorrosive

Hydrogen is also the lightest gas. Because it's 14 times lighter than air, it rises and disperses rapidly—at speeds of almost 20 meters per second (44 miles per hour)—a property known as buoyancy.

### Image

## General Hydrogen Properties

Hydrogen is a flammable gas, so it must be stored properly away from heat, flames, and sparks.

When hydrogen burns in air, it doesn't produce smoke. Its pale blue flame is difficult to see; in fact, in daylight, the human eye can barely detect it. And although a hydrogen flame burns just as hot as those of other common fuels, it radiates less heat and is less likely to start secondary fires.

## **Fuel Comparison**

In general, hydrogen is neither more nor less hazardous than common fuels like natural gas, propane, and gasoline. It is, though, less familiar to most people. The text below compares hydrogen to other fuels we use today.

Hydrogen has no odorant added, is non-toxic, has a vapor density (% relative to air) of 0.07, has an autoignition temperature of 1,085°F (585°C), has an ignition energy (mJ) of 0.02, and has a flammability range (% in gas-to-air volume ratio) of 4 to 75.

Natural gas has odorant added if compressed but not if liquefied, is non-toxic, has a vapor density of 0.55, has an autoignition temperature of 1,003° (540°C), has an ignition energy of 0.29, and has a flammability range of 5 to 15.

Propane has odorant added, is non-toxic, has a vapor density of 1.52, has an autoignition temperature of 914°F (490°C), has an ignition energy of 0.26, and has a flammability range of 2.1 to 10.1.

Gasoline has no odorant added, is toxic, has a vapor density of 4.00, has an autoignition temperature of 450°F (232°C), has an ignition energy of 0.24, and has a flammability range of 1.4 to 7.6.

More than 9 million tons of hydrogen are produced and used in the United States each year. Hydrogen is used in petroleum refining, aerospace applications, pharmaceuticals, petrochemical manufacturing, and the food and semiconductor industries. It's also used in fertilizer production, for glass purification, in welding, and in power generators.

Currently, we use only a small percentage of the hydrogen we produce as a fuel. As hydrogen applications become more common, though, demand for hydrogen will rise. Researchers around the country are exploring numerous ways to supply our future hydrogen needs.

## **Thermochemical Hydrogen Production**

Hydrogen is most often produced through thermochemical processes, which use heat to separate hydrogen from its source.

### **Natural Gas Reforming**

About 95% of the hydrogen produced in the United States today is created through steam methane reforming. In this process, high-temperature steam and heat are used to separate hydrogen from a methane source, usually natural gas. An alternative method, called partial oxidation, reacts methane and other hydrocarbons found in natural gas with oxygen to produce synthesis gas, from which hydrogen can be separated.

### **Gasification**

Gasification involves applying heat, pressure, and steam to convert coal or biomass into a gaseous mixture of hydrogen, carbon monoxide, carbon dioxide, and other compounds. Absorbers then separate the hydrogen from the gas mix.

### **Renewable Liquid Fuel Reforming**

Like natural gas reforming, renewable liquid fuel reforming uses high-temperature steam to create a gaseous mixture of hydrogen and carbon monoxide. In this case, however, the source is a renewable fuel such as bio-oil or ethanol.

## Electrolytic Hydrogen Production

Electrolytic hydrogen production methods use electricity to split water (H<sub>2</sub>O) into hydrogen (H<sub>2</sub>) and oxygen (O). When the process is reversed, hydrogen and oxygen are combined to produce electricity and water.

## Hydrogen Delivery

Today, almost all hydrogen is produced on the site where it is to be used in a practice called captive use. This is particularly common at industrial sites where hydrogen is used in manufacturing processes. For some applications, though, hydrogen is delivered from off site. The delivery method depends on the distance to be traveled.

### Pipeline

Although pipelines are the least expensive method for delivery hydrogen in large quantities, they're also the least common. Hydrogen pipelines are expensive to construct, and few regions currently have the hydrogen demand to justify their expense. In the United States today, approximately 700 miles of hydrogen pipelines are centered in a few high-use regions near large petroleum refineries and chemical plants.

### High-Pressure Tube Trailer

High-pressure tube trailers are used to transport compressed hydrogen gas at pressures up to 3,000 psi (200 bar), with payloads ranging in size from 25,104 to 75,311 standard cubic feet. Because of the limited amount of hydrogen that can be transported at this pressure, though, the use of tube trailers is economically constricted to about a 200-mile radius from the point of production. Compressed hydrogen gas can also be delivered by rail, ship, or barge.

### Liquefied Hydrogen Tanker

Because liquefied hydrogen is denser and has a higher energy content than compressed hydrogen gas, it can be transported more economically over long distances. Liquefied hydrogen—known as cryogenic liquid hydrogen or LH<sub>2</sub>—is commonly transported in superinsulated cryogenic tanker trucks. It can also be delivered by rail, ship, or barge.

### Mobile Refueler

Mobile refuelers are transportable, trailer-mounted units typically used to deliver hydrogen to remote areas or those with lower demand. Mobile refuelers store and sometimes even produce their own hydrogen for distribution at the point of use. But because of the small amount of hydrogen they hold, mobile refuelers are generally the most expensive hydrogen delivery option.

## Hydrogen Storage

Hydrogen has a very high energy content by weight (about three times more than gasoline), but a very low energy content by volume (about four times less than gasoline). As a result, storing hydrogen—particularly within the size and weight constraints of a vehicle—is challenging. All systems for storing and handling hydrogen are designed with safety in mind.

Today, hydrogen is commonly stored and transported in two ways. The two most common forms of hydrogen fuel are compressed hydrogen gas and cryogenic liquid hydrogen.

## Compressed Hydrogen Gas Storage

Industry commonly compresses and stores hydrogen gas at pressures of about 2,000 psi (140 bar). Hydrogen used to fuel vehicles is typically compressed, stored, and dispensed at pressures of 5,000 psi (350 bar) or 10,000 psi (700 bar). At fueling stations, gaseous hydrogen is compressed in stages, and the pressurized hydrogen is stored in banks of containers that allow the hydrogen to be cascaded in increments of pressurization.

## Onboard Compressed Hydrogen Gas Storage

Vehicles that feature high-pressure onboard storage are equipped with tanks reinforced with carbon fibers. These tanks are composed of several layers. The innermost layer is either aluminum or a polymer with a high molecular weight. The next layer is a carbon-fiber/epoxy-resin shell, which bears the pressure load. Finally, an outer shell protects against impacts and damage. Tanks are equipped with a thermally activated pressure regulator.

## Compressed Hydrogen Gas System Safety

The text below describes the unique characteristics of compressed hydrogen gas, the potential hazards associated with it, and the safety measures designed into compressed hydrogen gas systems.

Hydrogen is colorless, odorless, and tasteless, so it is potentially hazardous because it is undetectable to human senses. Detection sensors can be used as a safety measure.

Hydrogen has a low viscosity and small atoms that can be absorbed into materials, so leaks and embrittlement of certain materials are possible, which can result in structural failure. Leak-detection systems, ventilation, and material selection can be used as safety measures.

Hydrogen also has low volumetric energy density, so it is potentially hazardous when stored at high pressures. Storage container design and pressure-relief devices can be used as safety measures.

Hydrogen is not breathable, so it can accumulate in confined spaces and act as an asphyxiant like any other gas that displaces oxygen. Ventilation and leak-detection systems can be used as safety measures.

Hydrogen has a wide flammability range of 4 percent to 75 percent, so leaks of all sizes are a concern. Ventilation and leak-detection systems can be used as safety measures.

According to hydrogen's properties, the energy required to ignite hydrogen is very low compared to other fuels, so ignition by a small spark is possible under some conditions. Ventilation, grounding, and removal of possible ignition sources can be used as safety measures.

Hydrogen burns with a pale blue flame that is nearly invisible in daylight, produces no smoke, and emits little heat, so there is potential for undetected flames. Flame detectors and leak-detection systems can be used as safety measures.

## Cryogenic Liquid Hydrogen

Hydrogen can also be stored as liquid fuel. In this case, hydrogen gas is cooled until it reaches  $-423^{\circ}\text{F}$  ( $-252.9^{\circ}\text{C}$ ) and turns to liquid (a process called liquefaction). Because liquid hydrogen is denser than hydrogen gas, it contains more energy per unit of volume. In fact, the volume ratio of liquid hydrogen to hydrogen gas is 1:848.

But the energy required to liquefy hydrogen constrains its use. The necessary energy is equal to about 30% of the energy content in the liquid hydrogen fuel. This method, therefore, is normally used only to transport large amounts of hydrogen. Researchers are working on improved liquefaction methods that will bring liquid hydrogen fuel into more widespread use.

## **Cryogenic Liquid Hydrogen System Safety**

This text outlines the unique characteristics of cryogenic liquid hydrogen, the potential hazards associated with it, and the safety measures that are designed into storage and handling systems.

Hydrogen has a low liquefying temperature (-423°F, -252.9°C), so cryogenic burns and lung damage are possible. System design, leak-detection systems, and personal protective equipment can be used as safety measures.

Hydrogen undergoes rapid phase change from liquid to gas, so pressure explosions are possible. System design, pressure-relief devices, and ventilation can be used as safety measures.

## Fuel Cell Benefits

Fuel cells have a number of advantages over traditional technologies:

- Reductions in electric grid losses and easing of distribution system bottlenecks, leading to enhanced reliability and quality of electricity
- Less fuel consumption per mile than vehicles with internal combustion engines
- Longer run times than battery systems
- Cogeneration of energy and heat in combined heat and power applications for buildings
- Zero to near-zero levels of harmful emissions from vehicles and power plants
- High energy density and long-lasting power in a compact package for portable power applications
- No recharging time
- Quiet operation

## Summary

Congratulations! You've completed the Hydrogen and Fuel Cell Basics section of this course. In this section, you learned about hydrogen properties, production, delivery, storage, and fuel cells.

Although using hydrogen as a consumer fuel is a relatively new concept, the United States produces millions of tons of hydrogen each year and has been using it safely in a wide variety of industrial applications for decades. Hydrogen has become part of our nation's long-term energy strategy, not only because it can be used as a transportation fuel, but also because it can power fuel cells that generate electricity and heat in stationary and portable applications of varying sizes.

Now, take the quiz.

## Hydrogen Internal Combustion Engines

With only modest design modifications, an internal combustion engine (ICE) can run on hydrogen. And because hydrogen contains no carbon, these engines don't emit carbon dioxide or other carbon compounds that contribute to climate change. In fact, the emissions from hydrogen-powered internal combustion engines are near zero.

Hydrogen-powered internal combustion engines offer several advantages:

- They perform well under all weather conditions
- They start easily in cold weather, even at subzero temperatures
- They don't need to be warmed up
- They use fuel efficiently

## Hydrogen Fuel Cells

The fuel cell—an energy conversion device that can capture and use hydrogen efficiently—will be an essential element of our energy future.

Hydrogen-powered fuel cells (“hydrogen fuel cells”) have enormous potential, not only to replace the internal combustion engine in vehicles, but also to generate electrical power in both stationary and portable applications. And because hydrogen is such a versatile energy carrier, we can actually revolutionize the way we energize our nation by harnessing hydrogen power on a large scale.

Like batteries, hydrogen fuel cells convert chemical energy into electrical energy and heat. But, unlike batteries, fuel cells don't need recharging; instead, they use hydrogen to produce continuous power.

They're also relatively modular, quiet during operation, and energy efficient (with two to three times the efficiency of traditional combustion technologies). Finally, hydrogen fuel cells are pollution-free, generating electricity with only water and potentially usable heat as by-products.

## Types of Fuel Cells

As the technology has evolved, researchers have developed different fuel cell designs to meet different needs. Fuel cells are classified primarily by the type of electrolyte they use. This determines, for example, the kind of chemical reactions that take place within the cell, the type of catalysts required, and the temperature range in which the cell operates. These design and operating characteristics, in turn, determine which type of fuel cell is best for which application.

The five most common types of hydrogen fuel cells are:

- Polymer electrolyte membrane (PEM)
- Phosphoric acid (PAFC)
- Solid oxide (SOFC)
- Molten carbonate (MCFC)
- Alkaline (AFC)

The following compares the five types of fuel cells.

Polymer electrolyte membrane fuel cells have an operating temperature between 50°C and 100°C (122°F and 212°F). System output is between <1 kW and 250 kW. Applications include portable power, small distributed generation, transportation, and specialty vehicles. Advantages include the fact that having a solid electrolyte reduces corrosion and electrolyte management problems, low temperature, and quick start-up.

Alkaline fuel cells have an operating temperature between 90°C and 100°C (194°F and 212°F). System output is between 10 kW and 100 kW. Applications include military and space uses. Advantages include the fact that cathode reaction is faster with an alkaline electrolyte—which leads to higher performance—and the fact that they can use a variety of catalysts.

Phosphoric acid fuel cells have an operating temperature between 150°C and 200°C (302°F and 392°F). System output is between 50 kW and 1 MW (or 250 kW for a typical fuel cell module). Applications include distributed generation. Advantages include higher overall efficiency with combined heat and power (or CHP), and increased tolerance to impurities (non-hydrogen constituents) in the hydrogen fuel.

Molten carbonate fuel cells have an operating temperature between 600°C and 700°C (1,112°F and 1,292°F). System output is between less than 1 kW and 1 MW (or 250 kW for a typical fuel cell module). Applications include electric utility and large distributed generation. Advantages include high efficiency, fuel flexibility, the fact that they can use a variety of catalysts, and the fact that they are suitable for combined heat and power.

Solid oxide fuel cells have an operating temperature between 600°C and 1,000°C (1,202°F and 1,832°F). System output is between less than 1 kW and 3 MW. Applications include auxiliary power, electric utility, and large distributed generation. Advantages include high efficiency, fuel flexibility, the fact that they can use a variety of catalysts, the fact that having a solid electrolyte reduces electrolyte management problems, the fact that they are suitable for combined heat and power, and hybrid or gas turbine cycle.

## Fuel Cell Applications

Hydrogen fuel cells can be scaled for use in a variety of applications—large and small, stationary and portable:

- Small, portable fuel cells (20–100 W) can power cell phones, laptops, MP3 players, and other electronic devices
- Medium-sized portable fuel cells (8–125 kW) can propel cars, trucks, buses, and specialty vehicles like forklifts
- Small stationary fuel cells (1–5 kW) can power homes and supply backup power for telecommunications and emergency response radio towers
- Large stationary fuel cells (200 kW–10 MW or more) can generate base-load electricity and heat.
- Very large stationary fuel cells (1–200 MW or more) can distribute electricity across the existing grid

## Portable Applications

Portable fuel cells can power almost any mobile application that typically uses batteries. Small (“micro”) fuel cells for portable power are among the first applications available to the public. In demonstrations, micro fuel cells have powered cell phones up to 30 days and laptops up to 20 hours without recharging, using a single fuel cartridge.

And larger fuel cells (15–100 W) can be incorporated into portable generators, supplying power for, as an example, mobile military operations.

## Stationary Applications

Stationary fuel cell systems are already generating power for industrial and commercial applications around the globe. They're used, for example, to supply base-load electric power, backup power, and power for remote or off-the-grid locations, as well as in combined heat and power systems.

### Base-Load Electric Power

Fuel cells can supply high-quality base-load electricity to homes as well as industrial and commercial facilities. To date, approximately 600 systems of 10 kW or more have been built and operated around the globe, and thousands of smaller systems have been installed and demonstrated as well. These systems operate silently and can run independently of or in parallel with the power grid. Today's systems typically run on natural gas, but the long-term goal is to use hydrogen directly, avoiding the use of natural gas or liquefied petroleum gas entirely.

In the United States, fuel cells are also used to generate base-load power at landfills and wastewater treatment plants, where they have proved to be a valid technology for reducing emissions and producing power from waste methane gas.

### Backup Power

When the electric power grid fails, fuel cells can step in, supplying backup power that keeps critical systems running. For example, emergency preparedness and response operations depend on the reliability and quality of first responders' energy supplies. If the primary grid power goes down, so can 911 and emergency communication centers, first responder stations, hospitals, control centers, and traffic signals, along with vital infrastructure components like water pumping and filtration systems. Fuel cells stand ready to furnish backup power for all of these.

The telecommunications industry also uses fuel cells for backup power. These fuel cells generate direct current (DC) power—without noise or emissions—for switch nodes, cell phone towers, and other electronic systems. They're also durable and function well at sites that are hard to access, subject to bad weather, or both.

### Remote or Off-Grid Power

Because they're durable and require little maintenance, fuel cells are ideal for producing power in remote locations. Today, fuel cells are being demonstrated in applications like railroad crossing lights and fire-watch towers. In the future, they may be used to power remote homes and cabins.

### **Combined Heat and Power**

Fuel cells can generate power not only to meet base loads, but also to run combined heat and power systems. These systems take advantage of the waste heat produced by the fuel cells to heat water and warm living or working spaces.

## Transportation Applications

As we move further into the 21st century, fuel cells will find perhaps their most important use in transportation. Fuel cells can be used to power a variety of vehicles, from the family car, long-haul truck, and transit bus to trains, planes, and boats.

More than 50 fuel cell buses have already hit the road in demonstration projects around the world. Fuel cells are efficient, so even if the hydrogen they run on is produced from fossil fuels, fuel cell buses can reduce carbon dioxide emissions.

Modern heavy-duty trucks are equipped with many electrical appliances, including computers, televisions, stereos, refrigerators, microwaves, heaters, and air conditioners. To power these devices when trucks are parked, drivers often idle their engines—a practice that’s unnecessary when using onboard fuel cells as auxiliary power units.

## Transportation Applications

Specialized equipment and vehicles like forklifts and industrial movers can operate on fuel cells, transporting people and goods in indoor and outdoor environments. Fuel cells in these applications are less than 100 kW and can be expected to operate 2,000 to 5,000 hours per year with zero or low emissions.

And personal transport vehicles like scooters, wheelchairs, motorcycles, and bicycles can also run on fuel cells. Manufacturers are interested in fuel cells for this type of equipment because they offer low emissions and high reliability.

## Summary

Congratulations! You've completed the Hydrogen and Fuel Cell Applications section of this course. In this section, you learned about the characteristics and advantages of the different types of fuel cells. You also began to discover the many ways hydrogen fuel cells can contribute to a reliable and secure energy future, in applications large and small, modes portable and stationary, and usages that run the gamut from power plants to bicycles.

Now, take the quiz.

## Hydrogen Fueling Stations

Construction and operation approvals typically require permits from several different agencies responsible for implementing codes and standards for fire safety, general building safety, waste water discharge, air quality, public health, and other areas. These permitting processes involve a number of steps that are generally included in the graphic below.

### Image

Graphic showing three general steps in the order of the permitting process: project considerations, construction approval, and operation approval.

In this section, we will focus on the construction and operation approvals.

While a hydrogen fueling station is still on the drawing board, developers conduct a safety analysis to analyze, quantify, and mitigate potential risks.

Safety planning tools include:

- Failure modes and effects analysis (FMEA)
- What-if analysis
- Hazard and operability analysis (HAZOP)
- Checklist analysis
- Fault tree analysis
- Event tree analysis
- Probabilistic risk assessment (PRA)

## Construction Approval

A number of national codes and standards govern requirements for the general design and layout of hydrogen fueling facilities.

For example, model code provisions cover:

- Fueling station design
- Equipment design (including listing and labeling)
- Barrier wall design, orientation, and construction
- Weather protection

## Setbacks and Footprints

Just like any station that dispenses transportation fuel, hydrogen fueling stations have setback and footprint requirements that influence station layout and design. These provisions differ for hydrogen gas and liquid hydrogen systems.

## Equipment and Specifications

National codes and standards specify requirements for equipment and installation at hydrogen fueling stations to ensure that hydrogen is produced, stored, and dispensed safely.

Equipment used with liquid and gaseous hydrogen fuels must be selected and installed according to these requirements. The station must protect people from injury by putting measures in place that detect hydrogen leaks early and rapidly detect and suppress hydrogen fires.

Like other fuels, hydrogen has specific properties that determine the appropriate equipment and specs for its use. Hydrogen fueling stations are equipped with pressure relief devices including rupture disks, pressure relief valves, and safety vents. Vent stacks are standard for liquid hydrogen storage systems; excess gaseous hydrogen (created from boiloff of liquid to gas) is routinely vented, a practice commonly known as “burping.”

Monitoring, controlled access, and emergency stops and shutoffs can also add a level of safety. Keep in mind, too, that using incompatible materials or installing equipment improperly can lead to fuel contamination, which can degrade the performance of the fuel cells that power hydrogen-fueled vehicles. Incompatible materials can also cause blistering or embrittlement, which can result in leaks.

## Hydrogen Delivery and Storage

Like gas stations, hydrogen fueling stations can have their hydrogen delivered. Typically, trucks deliver the fuel as a compressed gas or a liquid.

At the station, hydrogen gas is stored in banks of aboveground containers that must meet strict functional and operational requirements. Liquid hydrogen is stored in special double-walled, vacuum-insulated storage vessels that can be sited above or below the ground.

Hydrogen stations typically combine bulk storage and dispensing. They may provide gaseous hydrogen, liquid hydrogen, or both to cars, buses, or other types of vehicles.

## On-Site Production

Today, hydrogen fueling stations can produce hydrogen on site through either natural gas reforming or water electrolysis. On-site production eliminates the need for transporting the fuel to the station.

Because of the unique properties of hydrogen, special safety considerations are necessary. Several possible codes and standards can come into play for on-site hydrogen production.

## Dispensing Hydrogen Fuel

Fueling a hydrogen vehicle is similar to filling up a compressed natural gas vehicle, which many drivers now do every day all around the country. Like compressed natural gas fueling systems, hydrogen vehicles are fueled in a closed-loop system. The dispensing nozzle “locks on” to the vehicle receptacle before any hydrogen will flow.

Hydrogen dispensing nozzles are unique to particular operating pressures, so nozzles specific to one pressure can’t physically connect to vehicles with onboard storage at a different pressure.

And like natural gas systems, hydrogen dispensers are equipped with safety devices including breakaway hoses, leak detectors, and electrical grounding mechanisms. These types of controls help when people make mistakes, like trying to drive away while the nozzle is still connected to the vehicle.

## Balance-of-Plant Components

“Balance-of-plant” is the name given to the components of a hydrogen fueling station that aren’t part of the major functional systems.

National codes and standards address balance-of-plant components like:

- Piping and tubing
- Valves and fittings
- Pressure relief
- Venting and other equipment

## **Operation Approval**

A “permit of occupancy” issued from the local building department marks the conclusion of the construction approval process.

Operation approval, however, is an ongoing process that addresses safe operating conditions, maintenance, and record-keeping. Fire safety and inspection officials usually grant these approvals.

## Safety

The bottom line at a hydrogen fueling station, just like at any transportation fuel facility, is the safety of employees, customers, and passersby. Codes and standards are designed to reduce the probability of an unintentional hydrogen release, the consequences of any such incident, and the severity of a hydrogen-related fire.

Toward this end, hydrogen fueling stations incorporate fire suppression systems, alarms, sensors, gas detectors, and other safety equipment, all of which must be tested regularly. In addition, safety signs must be properly posted at all stations.

## Image

## Safe Operating Practices

To minimize the known hazards associated with handling hydrogen, safe operating practices have been established. An operations safety plan, which is part of standard safe operating practices, explains what to do if there's an incident.

## Annual Inspections

These inspections, which are required to ensure the continued safety of the hydrogen fueling facility, are usually included in the operation approvals.

Annual inspections may focus on:

- Specific operating equipment, subsystems, and systems inspections
- Fire protection and safety systems inspections
- Record-keeping inspections
- Operator training and performance

## Hydrogen Fueling Station Layout

This interaction provides an example of a typical hydrogen fueling station layout along with some of the setback requirements, codes and standards that govern the design, construction, and operation of such a station.

The animation is a map-like drawing of an example hydrogen fueling station. A food market and two parking lots are located in the upper-right corner of the lot. A car wash, a parking lot, and a trash enclosure are located on the left side of the lot. A fuel-dispensing island with a canopy is located in the bottom-right corner of the lot. A secondary street is located along the right side of the lot, and a primary street is located along the bottom of the lot.

Setback distances are indicated by colored regions and are summarized in a setback table titled "2016 National Fire Protection Association (NFPA) Setbacks":

- NFPA 2, Table 8.3.2.3.1.6 (A) – Minimum Distance from Bulk Liquefied Hydrogen (LH2) Systems to Exposures:
  - Wall adjacent to system constructed of combustible material (1,500 liter liquid hydrogen storage tank) – 50 feet
- NFPA 2, Table 7.3.2.3.1.1(a) – Minimum Distance (D) from Outdoor [GH2] Systems to Exposures:
  - Air intake openings – 34 feet
  - Wall openings – 34 feet
  - Lot lines – 34 feet
  - Parked vehicles – 16 feet
  - Building (with combustible walls) – 14 feet

## Specialty Vehicles—Fuel Cell Forklifts

Many organizations—grocers, tire and hardware companies, and others—have begun to realize the value of using fuel cells to support their operations. Federal agencies across the country are incorporating advanced energy technologies, including fuel cells, into their facilities.

For specialty vehicles such as forklifts, fuel cells can be a cost-competitive alternative to traditional lead-acid batteries because:

- Batteries have a limited range, take substantial time to recharge and cool before reuse, and are prone to voltage drops as power discharges.
- Unlike battery powered vehicles, fuel cell vehicles can be rapidly refueled, eliminating the time and cost associated with swapping batteries.
- The voltage delivered by the fuel cell is constant as long as hydrogen fuel is supplied. Using fuel-cell-powered forklifts can boost productivity by eliminating trips to the battery changing station. And with no need for battery chargers, storage, or changing areas, more warehouse space is available for other uses.

## On-Site Hydrogen Generation for Indoor Fueling Facilities

Some facilities generate hydrogen on site using a steam methane (natural gas or biogas) reforming (SMR) process.

The hydrogen generation and storage equipment consists of the following components:

- Hydrogen generation equipment—Water and gas (natural gas or biogas) purification system, steam reformer, and hydrogen purification system
- Storage equipment—Hydraulic compressor and cascade storage system

## Delivered Hydrogen for Indoor Fueling Facilities

Instead of generating hydrogen on site, some fueling facilities have hydrogen delivered by a vendor. Such sites often have a combined liquid/gaseous hydrogen storage system outside the facility. Liquid hydrogen is vaporized to make gaseous hydrogen for use in specialty vehicles. The gaseous hydrogen is then piped into the facility for dispensing.

## Summary

Congratulations! You've completed the Hydrogen Fueling Stations section of this course. In this section, you learned about hydrogen fueling stations, which resemble those that dispense gasoline. And many of the hydrogen fueling stations of the future will expand on the existing fueling stations of today. In some cases, developers will simply add hydrogen pumps to the gasoline or natural gas pumps that are already in place. Other hydrogen fueling stations will be designed and constructed to offer only hydrogen.

And like other fueling stations, hydrogen stations must be designed, constructed, and operated to work with the properties of the fuel they offer. Some special equipment needs and unique site and safety considerations rest on hydrogen's unique properties. Developers and code officials alike are becoming more familiar with the basic properties, uses, and safety considerations of hydrogen, along with the methods used for acquiring, storing, and dispensing the fuel. This familiarity will build, in turn, a comprehensive understanding of the construction and safety considerations for hydrogen fueling stations, as well as the related codes and standards.

Now, take the quiz.

## Fuel Cell Facilities

Fuel cell systems are entering the commercial market in many places across the country. These systems can be broadly divided into two groups: power-only and cogeneration.

Power-only examples include fuel cells for backup power for critical uses such as telecommunications and emergency response radio towers.

Cogeneration examples that also provide water or space heating include continuous base-load power to supplement grid power for power-quality-sensitive loads such as high-tech manufacturing and peak shaving by high-volume electricity users like data centers.

## Backup Power Systems

Backup or uninterruptible power systems fueled by hydrogen are generally relatively small (less than 15 kW).

Typically serving as backup during grid failures, these systems usually use polymer electrolyte membrane (PEM) fuel cells that operate at relatively low temperatures. The hydrogen is most often stored in pressurized cylinders, with fuel delivered by swapping full cylinders for empty ones.

## Components of Typical Backup Power Systems

Graphic of a backup power system that uses a polymer electrolyte membrane (PEM) fuel cell stack to provide power for the load. The process requires two primary elements (air and stored hydrogen) and results in two products (power and a mixture of air and water). To generate power, the PEM fuel cell stack involves three primary processes: humidifying air, regulating hydrogen, and cooling the fuel cell.

The process of humidifying the air starts when air passes through the air filtration and the blower to the membrane humidifier. The humidified air moves from the membrane humidifier to the PEM fuel cell stack. The process of regulating hydrogen starts when stored hydrogen passes through the pressure regulator, into the membrane humidifier, and then into the PEM fuel cell stack. The process of cooling the fuel cell starts by passing coolant through the PEM fuel cell stack. The warmed coolant exits the PEM fuel cell stack through the coolant pump and enters the radiator. Fresh coolant exits the radiator and travels back to the PEM fuel cell stack to repeat the cooling process.

The PEM fuel cell stack releases air and water as a byproduct mixture on two sides. On the humidified air side, the stack releases an air and water mixture that passes through two membrane humidifiers before entering the dilution mixer. These byproducts then exit the power system as air and water. On the regulated hydrogen side, the stack releases an air and water mixture that splits into two directions. Some of this byproduct mixture re-enters the powering process through a recirculation pump. The rest of this byproduct mixture passes through the purge valve before entering the dilution mixture. The byproducts then exit the power system as air and water. The load takes power from the PEM fuel cell stack, uses what is necessary, and returns what is not used.

### Supplementary Content

#### Hydrogen Storage for Backup Power Systems

Backup power systems with polymer electrolyte membrane (PEM) fuel cells are usually fueled by one or more six-packs of delivered compressed hydrogen storage containers. Each container weighs about 137 pounds (lb) and holds either 196 or 261 standard cubic feet (scf) of hydrogen at a pressure of up to 2,400 pounds per square inch (psi). Each six-pack can power a typical 5-kW fuel cell for nearly 12 hours. The hydrogen can also be stored in permanent fuel tanks.

#### PEM Stack (Remote Monitoring)

Unlike batteries and generators, fuel cells can be monitored remotely. During an extended power outage, system managers can wait to service a facility until fuel is actually running low. Sometimes described as “moving refueling from an art to a science,” this can greatly reduce maintenance costs and allow facility managers to devote resources to the highest priority locations during outages.

#### Recirculation Pump

[Course Materials](#)   [Library](#)   [Exit](#)

[Hydrogen & Fuel Cell Basics](#)   [Hydrogen & Fuel Cell Applications](#)   [Hydrogen Fueling Stations](#)   [Fuel Cell Facilities](#)

A recirculation pump takes byproducts released by the stack and reintroduces them into the fuel cell through the membrane humidifier.

### **Membrane Humidifier**

Membrane humidifiers transfer water from the spent cathode exhaust through a membrane to the incoming hydrogen. The pressure drop across the membrane humidifier is controlled to prevent excessive mixing of the reactants. A membrane humidifier uses the energy from the spent air to raise the temperature and concurrently humidify the incoming air.

### **Dilution Mixer**

The dilution mixer takes products from the membrane humidifier and purge valve and releases exhaust.

## Supplementary Base-Load Power Cogeneration Systems

These large fuel cell systems have high operating temperatures so they can produce useful heat (or cooling) in addition to electricity. They are generally larger (100 kW to several megawatts [MW]), more complex systems that run continuously, ensuring consistent power quality as well as backup if the power goes out.

Systems like this can use phosphoric acid fuel cells (PAFC), molten carbonate fuel cells (MCFC), or solid oxide fuel cells (SOFC) with associated reformer units that allow them to run on natural gas or other hydrocarbon fuel.

## Components of Typical Supplementary Base-Load Power Cogeneration Systems

Most supplementary base-load power systems use phosphoric acid, molten carbonate, or solid oxide fuel cells. As the diagram shows, these large, continuous-operation systems generally include exhaust burners and exhaust and coolant condensers, as well as cogeneration system connections.

### Image

Graphic of a cogeneration power system that shows how three elements (air, fuel, and water) generate two products (AC power and water at about 80°C). The system is composed of six basic parts: an exhaust cooler, a burner, a fuel reformer, a fuel cell, a coolant cooler, and an inverter. The exhaust cooler uses water at about 60°C from buildings to cool warm exhaust from the burner and releases cold exhaust into the air and warmed water at about 62°C to the coolant cooler. The burner takes air, depleted air from the fuel cell, fuel, and depleted reformate from the fuel cell and releases warm exhaust to the exhaust cooler and heat to the fuel reformer.

The fuel reformer takes fuel, air, water and heat from the burner to release reformate to the fuel cell. The fuel cell takes reformate from the fuel reformer and air to release depleted air to the burner and DC power to the inverter. The fuel cell also takes cold coolant from the coolant cooler and releases hot coolant to the coolant cooler. The coolant cooler takes hot coolant from the fuel cell and water from the exhaust cooler at about 62°C to release cold coolant to the fuel cell and water at about 80°C to buildings. The inverter inverts DC power from the fuel cell to send AC power to buildings.

#### Fuel Reformer for Supplementary Base-Load Power Systems

Reformers generate hydrogen from hydrocarbon fuels. A fuel reformer or fuel processor produces relatively pure hydrogen from natural gas; lower purity methane similar to methane from landfills or anaerobic digesters; or any hydrocarbon fuel readily available or easily transportable (i.e., liquefied petroleum gas or diesel).

Converting liquid or gaseous light hydrocarbon fuels to hydrogen and carbon monoxide is commonly called reforming. Higher operating temperatures allow molten carbonate and solid oxide fuel cells to operate directly on methane while using a fuel cleanup or conditioning unit. Systems without separate reformers can divert some hydrogen to fuel vehicles or equipment (i.e., forklifts operating on fuel cells). Such systems cogenerate power, heat, and fuel.

[Course Materials](#)   [Library](#)   [Exit](#)

[Hydrogen & Fuel Cell Basics](#)   [Hydrogen & Fuel Cell Applications](#)   [Hydrogen Fueling Stations](#)   [Fuel Cell Facilities](#)

### **Inverter (Power-Conditioning Equipment)**

Fuel cells generate direct current (DC). If a fuel cell power system serves a facility that runs on direct current, only current and voltage controls are needed for power conditioning.

Most supplementary base-load fuel cell power systems, however, serve alternating current (AC) facilities. In these cases, power-conditioning equipment includes DC-to-AC inversion as well as current and voltage controls. Frequency-control equipment is also necessary for maintaining an acceptable level of harmonics output. Even if alternating current power inversion is required, direct current will likely also be used for the system itself. Running blowers, pumps, controls, and other auxiliary equipment on direct current before it's inverted is usually more efficient.

### **Cogeneration System (~80°C Water)**

In any electrical generation system, inefficiencies take the form of waste heat. And supplementary base-load fuel cell power systems operate at such high temperatures that their waste heat is hot enough to be easily captured for useful work. Most commonly, that waste heat is used for domestic hot water or space heating. It's also possible to convert heat into cooling via absorption or desiccant cooling systems.

Such cogeneration or combined heat and power systems can dramatically increase the already high efficiency of supplementary base-load power systems. For this reason, they're a major advantage for distributed electrical generation systems.

### **Burner**

As a component of a typical supplementary base-load power cogeneration system, a burner helps increase output by reheating gas turbine exhaust with little or no additional air. For this reason, burners can raise the efficiency of gas turbine cogeneration.

### **Fuel Cell**

A device that uses hydrogen and oxygen to create electricity through an electrochemical process.

## Construction Approval

Designers and developers of stationary fuel cell systems should follow all the design principles appropriate to facilities involving flammable fuels, compressed gases, and electrical and water supply equipment, but be cognizant of the specific properties of hydrogen as well.

Special stationary hydrogen facility safety systems commonly include pressure relief devices such as rupture disks, pressure relief valves, and safety vents; leak and flame detection; monitoring; controlled access; and emergency stops.

Here are some specific design and installation considerations:

- Fire safety
- Compressed hydrogen gas storage
- Electrical equipment
- Fuel lines
- Balance-of-plant equipment

## Fire Safety

The ability to prevent or quickly suppress fires is important for any system that uses liquid or gaseous fuel.

Hydrogen is no more dangerous than other fuels, but it is different. Because hydrogen is colorless and odorless and its flames are virtually invisible in daylight, sensors and other equipment or design considerations—while unnecessary for other facilities—are often required.

On the other hand, hydrogen is nontoxic and as the lightest gas, it disperses rapidly upward if released, so open, outdoor locations greatly reduce potential hazards.

## Compressed Hydrogen Gas Storage

For fuel cell backup power systems, hydrogen storage is a primary safety consideration. Hydrogen is stored in standard prefilled cylinders, which are delivered to the site, or in pressurized tanks that are refilled by delivery tankers.

## Electrical Equipment

In addition to the power-conditioning equipment discussed earlier, fuel cell installations include a variety of electrical equipment and connections, all of which must be considered in developing safe system design and operating procedures.

Smaller telecommunications installations will house power-conditioning equipment—as well as fuel cells and hydrogen cylinders—in cabinets such as these. Larger installations will house power-conditioning equipment inside buildings, along with telecommunication equipment.

## Fuel Lines

Piping that carries the fuel from the storage tank to the fuel cells is another important safety element. And large supplementary fuel cell systems will have fuel lines bringing natural gas or other fuel to the system. These fuel lines are subject to appropriate regulations and design considerations for those kinds of pipelines.

## Balance-of-Plant Components

Fuel cell systems include a variety of peripheral and safety equipment, all subject to appropriate safety and environmental regulations.

Large supplementary power systems also discharge cooling water associated with heat removal from the reformer and the fuel cell itself.

## **Operation Approval**

Fire codes generally require fuel cell power systems to be serviced once a year and many vendors find that sufficient to keep fuel cell backup power systems running at peak performance. Because the fuel cell itself has no moving parts (there are generally fans and other moving parts in the balance of the system), backup power fuel cell maintenance focuses on resupplying hydrogen fuel.

Large supplementary systems are directly connected to natural gas or other fuel supplies, so no fuel transportation or delivery is involved. These systems are, however, major pieces of equipment that should be regularly inspected for any needed maintenance.

Such systems also typically supply cogeneration heating or cooling as well as electricity, so all of these connections and auxiliary systems are subject to codes and standards and may require more frequent inspection and maintenance.

Specific operation considerations for stationary fuel cells include hydrogen delivery, fire and emergency planning, and periodic inspections.

## Delivery of Hydrogen for Fuel Cells

Most backup-power fuel cell installations are fueled by one or more six-packs of compressed hydrogen storage containers, but some may have permanent storage tanks.

When the hydrogen fuel supply runs low, a self-checking alarm remotely alerts the operator that the storage containers need to be replenished. The operator then makes arrangements to resupply via “hot swapping” or “bumping.”

In a hot-swap resupply, prefilled hydrogen storage containers are delivered to the fuel cell site and swapped one at a time with the depleted containers without disrupting backup operations. Bumping involves refilling permanent storage tanks at the site. A hydrogen tanker delivers hydrogen gas and replenishes the existing storage supply.

National codes and standards are in place to address hydrogen delivery; additional local regulations may apply as well.

## Fire and Emergency Planning

Effective planning for fires or other emergencies is one of the most important safety measures for any facility. It's particularly important for fuel cell facilities because emergency personnel may not be familiar with the fuels and equipment at such facilities. Site operations personnel should work with emergency responders to make sure they have the information they need to respond to a potential or actual incident.

## Periodic Inspections for Stationary Fuel Cell Power Systems

Codes and standards that govern periodic inspections are probably the most important general operation regulations for stationary fuel cell systems.

Periodic inspections may focus on:

- Specific operating equipment, subsystems, and systems
- Fire protection and safety systems
- Record-keeping
- Operating staff training

Congratulations! You've completed the Fuel Cell Facilities section of this course. In this section, you learned about stationary fuel cell applications. Whether small backup-power-only systems or large supplementary base-load power cogeneration systems, these systems involve hydrogen or other flammable fuels and various potentially hazardous components. They must be designed, constructed, and operated in accordance with established safety principles and the specific and unique properties of hydrogen. Additional federal, state, and local requirements may also apply.

Developers and permitting officials alike are becoming more familiar with fuel cells and with the basic properties, uses, and safety considerations of hydrogen, along with the methods for acquiring, storing, and dispensing the fuel.

## Glossary

### Adsorber

Solid material used to capture either a gas or liquid.

### Anaerobic digestion

A series of processes in which tiny organisms break down biodegradable material in the absence of oxygen.

### Anode

The electrode at which oxidation (a loss of electrons) takes place. For fuel cells and other galvanic cells, the anode is the negative terminal; for electrolytic cells (where electrolysis occurs), the anode is the positive terminal.

### Atom

The smallest particle of an element that can exist either alone or in combination.

### Autoignition

The spontaneous ignition of gases or vapors given off by a heated material.

### Autoignition temperature

Minimum temperature at which a substance must be heated without applying flame or spark. Materials should not be heated to greater than 80% of this temperature.

### Base load

The minimum amount of power that a utility or distribution company must make available to its customers, or the amount of power required to meet minimum demands based on reasonable expectations of customer requirements. Base-load values usually vary from hour to hour.

## Glossary (continued)

### **Biomass**

Organic matter, including crop or forest residues, organic municipal solid wastes, and special crops that can be grown specifically for energy production.

### **Bio-oil**

A carbon-rich liquid that can be derived from solid biomass through pyrolysis. The liquid can then be used to produce chemicals and fuels.

### **Boiloff**

The vapor loss from a volatile liquid such as hydrogen in its liquid form.

### **Buoyancy**

The tendency of a body to float or to rise.

### **Burner**

As a component of a typical supplementary base-load power cogeneration system, a burner helps increase output by reheating gas turbine exhaust with little or no additional air. For this reason, burners can raise the efficiency of gas turbine cogeneration.

### **Captive use**

The practice of producing hydrogen on the site where it is to be used.

## Glossary (continued)

### **Catalyst**

A chemical substance that increases the rate of a reaction without being consumed. After the reaction, it can potentially be recovered from the reaction mixture chemically unchanged. The catalyst lowers the activation energy required, which allows the reaction to proceed more quickly or at a lower temperature. In a fuel cell, the catalyst facilitates the reaction of oxygen and hydrogen. In polymer electrolyte membrane fuel cells, it is usually made of platinum powder very thinly coated onto carbon paper or cloth. The catalyst is rough and porous so that the maximum surface area of the platinum can be exposed to the hydrogen or oxygen. The platinum-coated side of the catalyst faces the membrane in the fuel cell.

### **Cathode**

The electrode at which reduction (a gain of electrons) occurs. For fuel cells and other galvanic cells, the cathode is the positive terminal; for electrolytic cells (where electrolysis occurs), the cathode is the negative terminal.

### **Checklist analysis**

A systematic evaluation against pre-established criteria in the form of one or more checklists.

### **Cogeneration**

A form of energy generation where the waste heat from electricity generation is passed through a second cycle to extract the energy from the heat. Also known as combined heat and power (CHP).

### **Compressor**

A device used for increasing the pressure and density of gas.

Glossary: Slide 3 of 10

[Publications](#)   [Related Links](#)   [Glossary](#)

## Glossary (continued)

### Density

The amount of mass in a unit volume. The density of gases varies with temperature and pressure.

### Dilution Mixer

The dilution mixer takes products from the membrane humidifier and purge valve and releases exhaust.

### Electrochemical process

A process that uses electricity to cause a chemical transformation.

### Electrolysis

A process that uses electricity passing through an electrolytic solution or other appropriate medium to cause a reaction that breaks chemical bonds.

### Electrolyte

A substance that conducts charged ions from one electrode to the other in a fuel cell, battery, or electrolyzer.

### Electrolyzer

A device that uses electricity to break water down into hydrogen and oxygen.

### Electron

A stable atomic particle that has a negative charge; the flow of electrons through a substance constitutes electricity.

## Glossary (continued)

### **Embrittlement**

The process by which various metals—most importantly high-strength steel—become brittle and crack after being exposed to hydrogen.

### **Energy**

The quantity of work a system or substance is capable of doing, usually measured in British thermal units or joules.

### **Energy carrier**

A means by which energy can be delivered and stored in a usable form. Energy carriers such as hydrogen and electricity are not primary energy sources. They must be produced from primary energy sources such as light, wind, and fossil fuels.

### **Energy content**

The amount of energy for a given mass of fuel.

### **Ethanol**

A liquid biofuel made by converting the carbohydrate portion of biomass into sugar, which is then converted to ethanol through a fermentation process similar to brewing beer. Ethanol is the most widely used biofuel today.

### **Event tree analysis (ETA)**

An inductive procedure that shows all possible outcomes resulting from an accidental (initiating) event in a complex system.

Glossary: Slide 5 of 10

## Glossary (continued)

### **Failure mode and effects analysis (FMEA)**

A deductive risk analysis method that helps identify and rank the type, severity, and priority of potential failures of a design or construction process.

### **Fault tree analysis (FTA)**

A deductive analysis method that results in a systematic description of the combinations of possible occurrences in a system that can result in failure. The method, which is applied as a diagnosis and development tool, is especially helpful in early design stages.

### **Flammability range**

The flammability range of a gas is defined in terms of its lower flammability limit and upper flammability limit. Between the two is the flammable range in which the gas and air are in the right proportions to burn when ignited. Below the lower flammability limit, there is not enough fuel to burn. Above the higher flammability limit, there is not enough air to support combustion.

### **Fuel**

A material used to create heat or power through chemical conversion in processes such as burning or electrochemistry.

### **Fuel cell**

A device that uses hydrogen and oxygen to create electricity through an electrochemical process.

### **Fuel reformer**

A device that uses heat and catalysts to “crack” hydrocarbons and release the hydrogen they contain. A reformer produces a mixture of gases that must then be purified to produce hydrogen pure enough for use in a fuel cell. Also called a fuel processor.

[Publications](#)   [Related Links](#)   [Glossary](#)

## Glossary (continued)

### **Galvanic**

Of, relating to, or producing a direct current of electricity.

### **Hazard and operability analysis (HAZOP)**

A methodology for identifying and dealing with potential problems in design, manufacturing, or industrial processes, particularly those that would create a hazardous situation or a severe impairment of the process.

### **Heat value**

The amount of heat that can be obtained from a fuel.

### **Ignition energy**

The amount of external energy that must be applied to ignite a combustible fuel mixture.

### **Ion**

An atom or molecule that carries a positive or negative charge because of the loss or gain of electrons.

### **Liquefaction**

The process of making or becoming liquid.

### **Membrane humidifier**

Membrane humidifiers transfer water from the spent cathode exhaust through a membrane to the incoming hydrogen. The pressure drop across the membrane humidifier is controlled to prevent excessive mixing of the reactants. A membrane humidifier uses the energy from the spent air to raise the temperature and concurrently humidify the incoming air.

## Glossary (continued)

### **Methane**

See natural gas.

### **Molecular weight**

The weight of a molecule that may be calculated as the sum of the atomic weights of its constituent atoms.

### **Molecule**

The smallest particle of a substance that retains all the properties of the substance. It is composed of atoms.

### **Natural gas**

A naturally occurring gaseous mixture of simple hydrocarbon components (primarily methane) used as a fuel.

### **Oxidation**

The loss of one or more electrons by an atom, molecule, or ion.

### **Polymer**

A natural or synthetic compound composed of repeated links of simple molecules.

### **Power conditioning**

The isolation of sensitive equipment from the effects of electrical noise and voltage fluctuations.

### **Primary energy source**

Source of energy found in nature, such as the sun, wind, and fossil fuels.

## Glossary (continued)

### **Probabilistic risk assessment (PRA)**

A systematic approach to evaluating how the pieces of a complex system work together to ensure safety, allowing analysts to quantify risks.

### **Proton**

A subatomic particle in the nucleus of an atom that carries a positive electric charge.

### **Pyrolysis**

A process in which the biomass is broken down into liquid in an oxygen-free, high-temperature environment.

### **Radiosonde**

A miniature radio transmitter that's carried aloft (like an unmanned balloon). Its instruments use precise tone signals or other suitable methods to broadcast the atmospheric humidity, temperature, and pressure every few seconds.

### **Recirculation Pump**

A recirculation pump takes byproducts released by the stack and reintroduces them into the fuel cell through the membrane humidifier.

### **Setback**

The absolute minimum distance that must be maintained between any energy facility and a dwelling, rural housing development, urban center, or public facility.

### **Six-packs**

Compressed hydrogen storage containers that each hold 139 or 261 scf of hydrogen at a pressure of 2,400 psi. Together, they can power a fuel cell for 24 to 96 hours.

## **Glossary (continued)**

### **Steam reforming**

The process of reacting a fuel such as natural gas or ethanol in the presence of steam to produce hydrogen.

### **Synthesis gas**

A mixture of hydrogen and carbon monoxide; also known as syngas.

### **What-if analysis**

A process in which key quantitative assumptions and computations (underlying a decision, estimate, or project) are changed systematically to assess their effect on the final outcome. Employed commonly in evaluation of the overall risk or in identification of critical factors, it attempts to predict alternative outcomes of the same course of action. Also called sensitivity analysis.
