The Business Case for Hydrogen-powered Passenger Cars: Competition and solving the Infrastructure Puzzle

Subproject 2: The Business Case for Hydrogen Fueling Stations: The 101th-of-a-kind case

Project ID # SA052

Robert Rosner, EPIC*, Dept. of Physics and Harris School of Public Policy
Robert Topel, EPIC* and Booth School of Business
Carlo Graziani, Physical Science and Computation Institute
The University of Chicago
June, 2016

*EPIC = Energy Policy Institute at Chicago
Overview

Timeline of Subproject
Start date: 01 March 2016
End date: Ongoing project

Budget
FY15 DOE Funds: $70K
FY16 DOE Funds: $72k
• Including partners

Barriers
1. Uncertain future market behavior (viz., fuel costs, # of H₂-powered cars sold in target markets)
2. Lack of existing market experience for H₂-powered passenger vehicles – and the as-yet unanswered question of market acceptability for H₂-fueled passenger vehicles
3. Inconsistent data, assumptions and guidelines in existing literature, for both H₂ filling station construction and operating costs
4. Unanticipated technological developments

Partners/Collaborators

* Funded partners:
  Univ. of Chicago faculty: Energy Policy Institute at Chicago [EPIC]*
  Univ. of Chicago Senior Research Associate: Carlo Graziani
  Univ. of Chicago student: Chuan Yin
  Argonne National Laboratory

* Collaborator for this subproject:
  NREL

* A joint program of the Booth School of Business, the Harris School of Public Policy and the Department of Economics, all at the University of Chicago
Relevance of this subproject

• A key question for the success of H₂-fueled vehicles is whether a plausible business case can be make for building out the H₂ filling station network, once the initial subsidies phase out
  – This will be needed to have VCs consider investing in this market
  – This is a key economic milestone for the DOE Hydrogen & Fuel Cells Program

• A complete business case analysis requires
  – Consideration of the various schemes for distributing H₂
  – Analysis of the various cost components for building out H₂ filling stations
    • Analysis of the opportunities for “learning”
    • Analysis of the cost savings accruing from operating H₂ filling station networks at scale
    • Probabilistic analysis of risk

  – This document provides a progress report on our 1st two months of study of this subproject
Approach: 1 – Steps and Status

1. Establish
   Build our team; identify data sets; and and our approach
   (2015, December)
   - Discuss approach with ANL and DOE-FCTO
   - Identify and hire collaborating students
   - Hire collaborating research associate (part-time)

2. Prototype
   Gather cost data sets for construction and operation
   (2016, March-April)
   - Discuss with ANL, NREL, H₂ providers
   - Collect initial data set for costs for building out 101st H₂ filling station and its operation

3. Prototype
   Develop first-cut 101st H₂ station deployment strategies
   (2016, April)
   - Develop analysis approaches for identifying and evaluating “learning opportunities” (e.g., “learn by doing”) for cost reductions
   - Identify cost reduction opportunities by operating at scale

3. Refine
   Vet data, carry out analyses, consider risk issues
   (2016, May-September)
   - Execute and validate data and analyses with stakeholders, including commercial vendors
   - Results framed as a business analysis for VC community
   - Sensitivity & uncertainty (risk) analyses
Approach: 2 – Program Interconnections and Deliverables

Analysis Framework
- H2A design parameters
- HDSAM design parameters
- OEM capital & O&M costs
- H2FAST input parameters
- Stakeholder experience/data
- 3rd party H2 vendor analyses

Models & Tools
- H2A
- H2FAST
- HDSAM/HRSAM
- UChicago business analysis tools

Stakeholder Analyses
- Station component manufacturers & operators
- Air Liquide
- Air Products

National Labs
- ANL – HDSAM/HRSAM
- NREL/SNL – H2FIRST

Stakeholders, FCTO & External Reviews

3rd Party Studies & Analyses
- NREL and ANL H2 station analyses

Outputs & Deliverables
- Independent assessment of costs and their uncertainties
- Business case statement for VC community
Accomplishments and Progress: Background

• Our overall project aims to establish the business case for investing in the HFCV market place for the VC community.
  • **First stage:** Examine the competitive outlook for HFCVs, based on existing data for fossil-fueled passenger vehicles, hybrids, BEVs and HFCVs
    • **Focus on extant data** – including provenance and uncertainties
    • **Adopted a “learn-by-doing” paradigm** for estimating future cost reductions in the various competing car technologies
    • **Used a probabilistic risk framework**, based on estimated uncertainties of the various cost component of the competing vehicles, in order to develop uncertainties for our vehicle cost predictions.
    • The next 3 slides provide examples of our results from this study.
  • **Second stage:** Focus on ROI for fueling infrastructure for HFCVs; this is the current study (started 1 March 2016), and is described in detail in subsequent slides.
  • **Third stage:** Monitor the H₂ vehicle market (principally in California) in order to probe whether we can confirm (or contradict) our various assumptions of “learn by doing” and “cost reductions at scale”
Accomplishments and Progress: Summary of results of our stage 1 study

• The essence of our competitive market analysis is illustrated by the two figures following slides.
  • Figure 1: Probability distribution function (PDF) for estimated Total Cost of Ownership of a Mirai HFCV in 2030, based on our estimated cost component uncertainties and the estimated effects of “learn-by-doing”.
  • Figure 2: Composite estimated Total Cost of Ownership for the competing vehicle technologies, together with uncertainties (obtained from the computed PDFs), for years 2020 through 2050, assuming no carbon tax or any other market interference by government.

• Key conclusion: In the absence of government interventions, HFCVs will not be competitive – as measured by the Total Cost of Ownership – until roughly the 2030s.
Illustrative result for Stage 1: PDFs

Total Cost ($) of Ownership for Toyota Mirai in 2030

Key assumptions:
• No gov’t market interventions
• Learn-by-doing
• All data input uncertainties accounted for
Illustrative result for Stage 1: Total cost of ownership comparisons

We assume:
- No gov’t market interventions
- Error bars derived from variance of computed PDFs
- “Learn-by-doing” applied, but differentially, depending on maturity of propulsion technology

N.b.: All vehicles listed have a range in excess of 300 miles, except for the BEV. The 2016 BEV chosen has a nominal range of 76 miles, which is believed to increase to 100 miles for the 2017 model year.

CNGV: Honda Civic NG Hatchback  BEV: Ford Focus Electric 4-door
HEV: Toyota Camry Hybrid XLE  HFCV: Toyota Mirai
Accomplishments and Progress: Background of 2nd Stage Study

- The present subproject focuses on H₂ fueling of HFCVs, and in particular entails examination the “101th-of a-kind” business case
  - *We focus on the business opportunities for delivering H₂ to the ultimate H₂-powered vehicle customer, assuming 100 H₂ fueling stations have already been established*
    - Analysis of extant data – including provenance, uncertainties, and technological readiness
      - Data include cost of constructing a H₂ fueling station as well as its operating costs
    - Identification of cost savings opportunities and economic and technical risks
    - Develop probabilistic risk framework
  - Two key assumptions will govern this work
    - First, the number of H₂-fueled vehicles in the target area will be known
    - Second, extant data will confirm (or contradict) our assumptions of “learn by doing” and “cost reductions at scale”

- Subproject started 1 March 2016; we report progress as of late April 2016
  - We have finished the ‘first-cut’ data gathering, including first cuts at identifying saving opportunities
Accomplishments and Progress: Results

BASED ON EARLIER WORK BY NREL AND ANL, OUR INITIAL CONCLUSIONS ARE:

• A 101th station only makes economic sense if the H₂ vehicle market shows evidence of accelerating
• In that case, an appropriate target delivery rate for the 101st station is 200-300 kg/day.
• At this fill rate, the H2FIRST Reference Station Design study (Pratt et al. 2015) strongly supports going with the “High Use Commuter” station model, based either on a 1-hose gaseous, or a 2-hose liquid H₂ filling station design.
• Since the 101st station will be built after considerable experience with the various alternative station designs has been gained, we assume that the target station designs for this study correspond to station numbers 1 (gaseous, 1-hose, 300 kg/day) and 5 (liquid, 2-hose, 300 kg/day) of Table 9 shown in Pratt et al. (2015).

</tbody>
</table>

• Note 1: Station design #5 requires a high-pressure cryo pump. Unfortunately, as Pratt et al. (2015) note, such a pump is not yet commercially available. We are consulting with cryo pump manufacturers to determine likely cryo pump costs, which are currently not known.
• Note 2: Current set-back distance restrictions on liquid H₂ stations lead to site size requirements economically inconsistent with high-capacity urban environments. We plan to investigate relaxation of these restrictions.
Collaborations

• Argonne National Laboratory
  – Prime contractor for UChicago activities and primary collaborator, inside the DOE Hydrogen and Fuel Cells Program
  – Is serving as our main technical support for H₂ fueling technology information
  – We work directly with the key ANL staff (including M. Mintz and M. Wang)

• Related collaboration
  – We have discussed our approach to the H₂ filling station market analysis with key NREL staff (including M. Melaina and M. Penev)
Remaining Challenges and Barriers

• Learning curves for constructing and operating $\text{H}_2$ filling stations are uncertain – however, at the time the 101\textsuperscript{st} station is to be build, sufficient data for developing such learning curves may be in hand in order to allow a more fact-based construction of

• $\text{H}_2$ costs remain highly uncertain
  – Optimal $\text{H}_2$ production technology is not yet established
  – Learning curve (“learn by doing”) is highly uncertain, and will depend on the nature of the $\text{H}_2$ production and distribution path chosen (cost reductions because of scale-up will not matter at this stage since $\text{H}_2$ volumes due to $\text{H}_2$ vehicle market remains relatively small)

• The dominant investment risk depends on the longer-term viability of $\text{H}_2$-fueled vehicles in the context of a concerted marketing effort on the part of battery-powered vehicles (BEVs)
  – The market segment, e.g., the retail price point at which $\text{H}_2$ vehicles are marketed, will be critical, esp. as BEVs selling for MSRP in the mid-$\$30K$ range come on market
  – A second significant investment risk is market acceptance: Safety concerns about $\text{H}_2$-fueled vehicles remain, and are likely to be stoked in the marketing competition with BEVs.
Proposed Future Work

• FY 16: Completion of business case analyses
  – Vetting of all input cost data
  – Bayesian analysis of construction and operation costs of two versions of high-capacity H₂ filling stations – one gaseous and one liquid
    • Our analysis will supplement the existing analyses of Pratt et al. (2015), replacing point estimates with probability distributions

• FY 17: Validation of business case analyses
  – Market analyses of roll-out of (a) alternative fuel vehicles (including BEVs and H (b) first-generation H₂ fueling stations during the FY15-17 period
    • Examine early evidence for “learn-by-doing”
    • Examine early evidence for gaining cost reductions from increasing scale of effort
    • Examine market acceptance
Summary Slide: Progress and Accomplishments in current fiscal year

1. **In the 1st two months** (03-04/2016) of our project, **we have completed** a “first cut” data gathering of the various cost components for the construction and operation of H₂ filling stations

2. **We are developing** a “first cut” analysis framework for a Bayesian analysis of the H₂ filling station total construction and operation costs
   
   i. This will allow replacement of point estimates with distributions
   
   ii. Together with an analysis of the projected costs of H₂ delivered to a given station, this will allow us to compute the ROI as a function of the volume (kg/day) of H₂ sold, together with its uncertainties
   
   iii. We also consider “learn-by-doing” opportunities for cost reduction. Key examples of such opportunities are offered by the build-out of supply chains for assembling H₂ filling station equipment, as well as the experience gained in the various means of producing and delivering
