

# Biomass to Hydrogen (B2H2)

**Pin-Ching Maness (P.I.)  
Katherine Chou (Presenter)  
National Renewable Energy Laboratory  
April 30, 2019**

DOE Hydrogen and Fuel Cells Program  
2019 Annual Merit Review and Peer Evaluation Meeting

**P038**

This presentation does not contain any proprietary, confidential, or otherwise restricted information.

# Overview

## Timeline and Budget

- Project start date: 10/1/2015
- FY16 DOE Funding: \$1M
- FY17 DOE funding: \$900K
- FY18 DOE funding: \$800K
- Total DOE funds received to date: \$2.7M
- The project will be closed out in FY19.

## Barriers

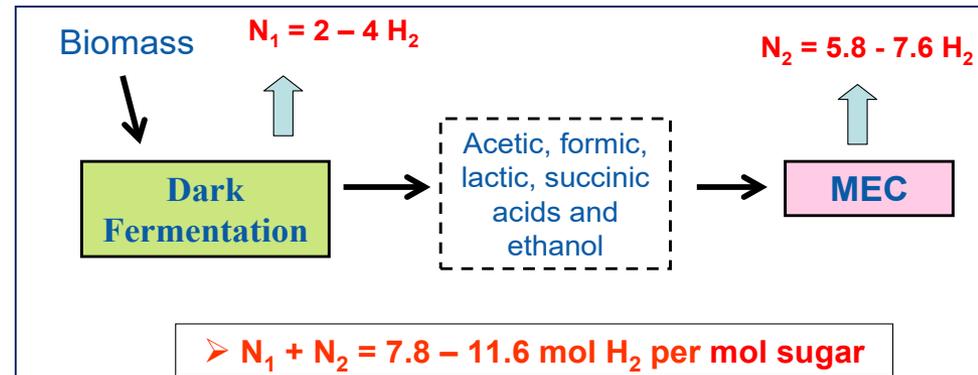

- H<sub>2</sub> molar yield (AX)
- Feedstock cost (AY)
- System engineering (AZ)

## Partners

- Dr. Bruce Logan  
Pennsylvania State University
- Drs. Steven Singer, Lawrence Berkeley National Lab (LBNL) and Ken Sale, Sandia National Lab (SNL)
- Dr. James Liao at UCLA (no cost)

# Relevance

**Overall Objective:** Develop *direct* fermentation technologies to convert renewable lignocellulosic biomass resources to H<sub>2</sub>.

## Current Project Year Objectives (May 2018 – April 2019)

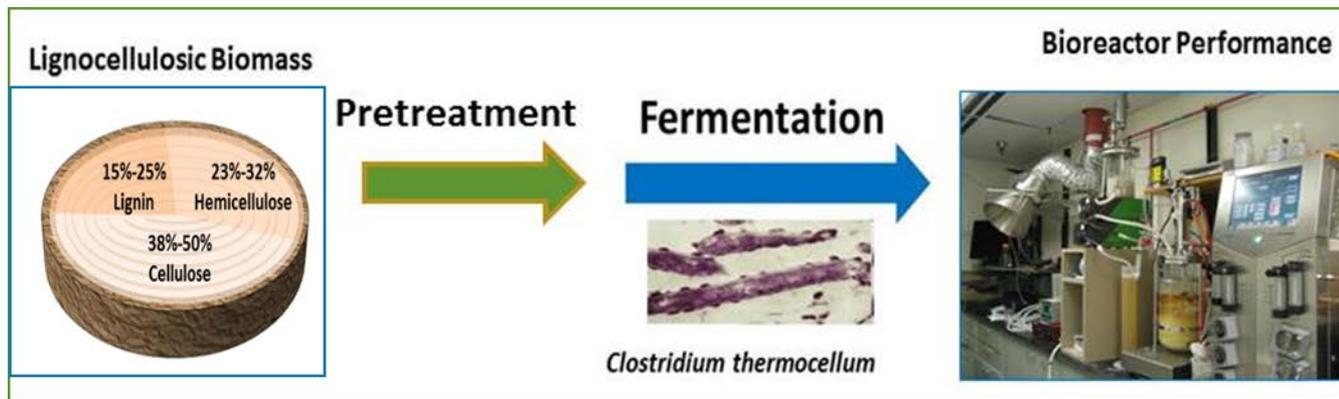

- **Addressing feedstock cost barrier**
  - Improve biomass utilization by converting cellulose (6-carbon sugar) and hemicellulose (5-carbon sugar) to produce H<sub>2</sub> either via co-culture systems or genetic engineering of *Clostridium thermocellum*.
- **Addressing H<sub>2</sub> molar yield barrier**
  - Had generated a series of competing-pathway mutants with either increased rate or yield of H<sub>2</sub>. Using <sup>13</sup>C-metabolic flux analysis, we aim to understand how these metabolic changes influence H<sub>2</sub> production to guide future genetic engineering strategies.
  - Microbial Electrolysis Cells (MEC): Replace the costly platinum cathode with inexpensive materials while still obtaining high rate of H<sub>2</sub> production, ultimately using fermentation waste – also addressing waste removal.

**This project addresses key DOE Technical Targets and leverages DOE Bioenergy Technologies Office (BETO) investment in biomass pretreatment.**

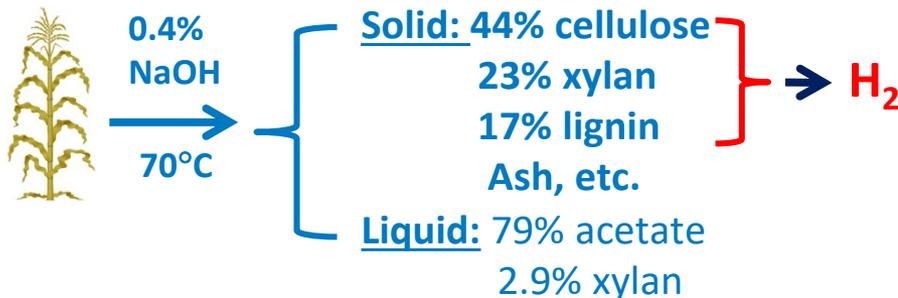

# Approach

## Task 1: Bioreactor Performance

- Approach:** Optimize bioreactor in batch and fed-batch modes by testing parameters such as corn stover lignocellulose loadings (DMR pretreatment), and hydraulic retention time (HRT), using the cellulose-degrading bacterium *Clostridium thermocellum* engineered to co-utilize both cellulose and hemicellulose.

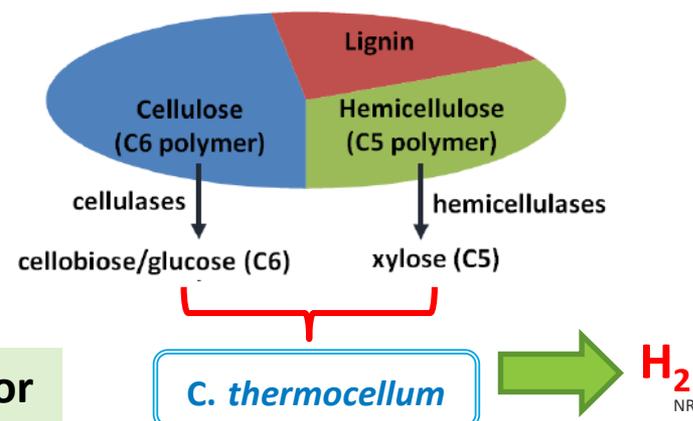

### Pretreatment – De-acetylated and Mechanically Refined (DMR)

**Ferment all the sugars to H<sub>2</sub> in one bioreactor**

### Engineer a Cellulose-Degrading Microbe to Co-Metabolize C5 Sugars

# Task 1. Accomplishments and Progress: Increased Xylan Biomass Utilization by 29% and H<sub>2</sub> Production by 45%.

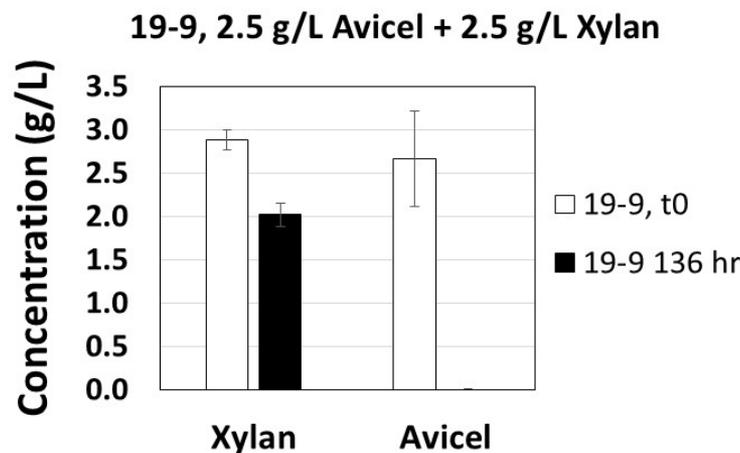

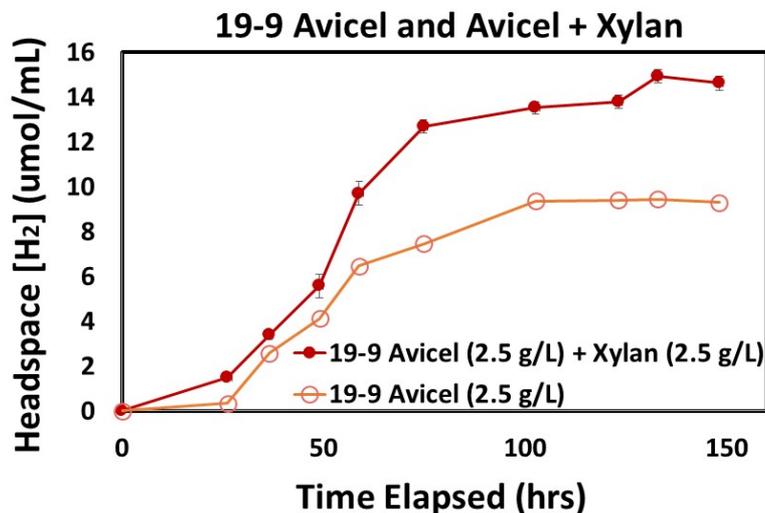

**FY18 Q4 Milestone**

Optimize and improve biomass utilization by 20% by developing methods to convert both C6 and C5 sugars to H<sub>2</sub>. We will achieve this by either using *C. thermocellum* already engineered to co-utilize both sugars, or in a binary culture including another microbe to metabolize the C5 sugar of the biomass feedstock

9/2018

**Complete**

- Use two strategies to improve biomass utilization:
  - The first approach is to use a binary co-culture system (reported in 2018 AMR).
  - A second approach is to express foreign xylose-pathways genes (*xyiAB*) to metabolize xylose, followed by adaptive evolution to utilize xylan (complex xylose).
- *C. thermocellum* evolved *xyiAB* strain (19-9) indeed utilized **29%** more xylan and produced 45% more H<sub>2</sub> by co-utilizing both cellulose and **xylan**.

Katherine Chou

Utilizing the hemicellulose portion of biomass will lower feedstock cost.

# Accomplishments and Progress : Increased H<sub>2</sub> production Rate by 15% and total H<sub>2</sub> by 16% in pH-controlled Bioreactor

<b>FY19 Q1 Milestone</b>	Via laboratory evolution, we have evolved the xylose-engineered strain to also degrade the more complex xylan, yet its performance in H <sub>2</sub> production has not been demonstrated in bioreactors. We will quantify H <sub>2</sub> production in pH-controlled bioreactor and obtain up to 10% increase in H <sub>2</sub> production (over a baseline rate of 1 L/L/d at 5 g/L substrate loading) as an indication of xylan utilization. We will also determine xylan utilization and profile metabolites to guide additional engineering strategies to improve xylan utilization.	12/2018	Complete
--------------------------	---	---------	----------

- The 19-9 evolved strain yielded an average H<sub>2</sub> production rate (over 43 h of fermentation) of 1024 mL/L-d using both cellulose and xylan, a **15% increase** over the parental controlled strain ( $\Delta hpt$ ) using cellulose only, and with a rate of 871 mL/L-d.
- The 19-9 evolved strain also produced **16% more** total H<sub>2</sub>.

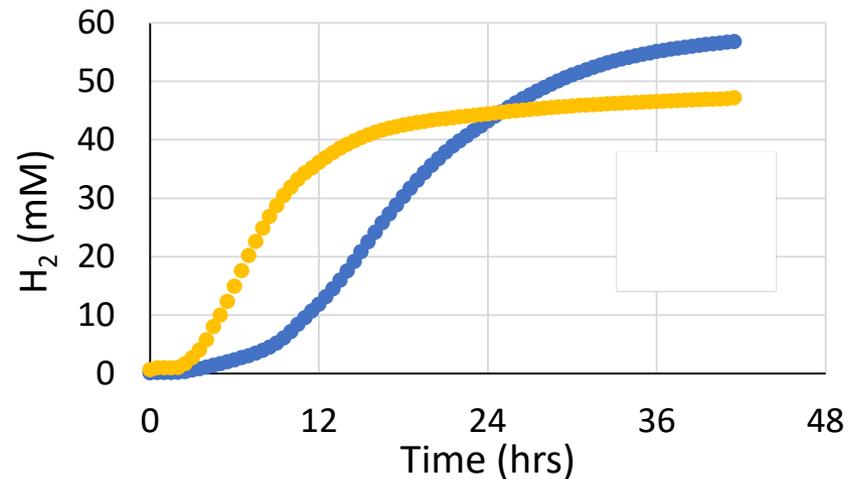

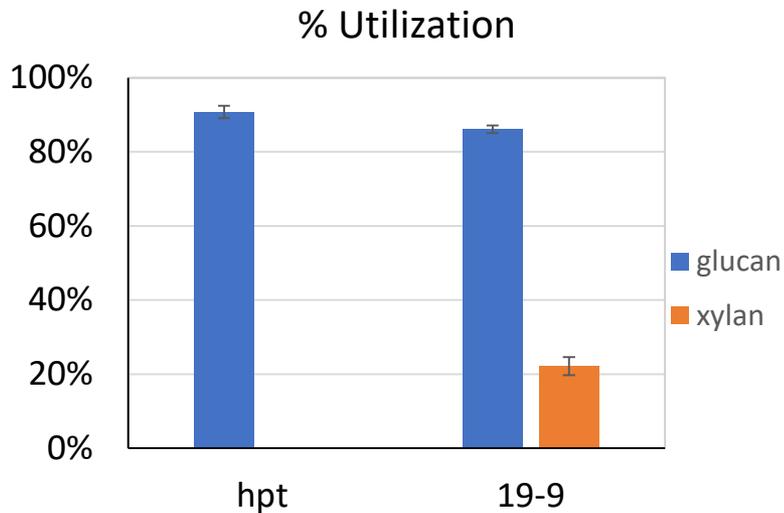

Strain	H <sub>2</sub> Production per Batch	Average H <sub>2</sub> Production Rate	Maximum 24 hr H <sub>2</sub> production rate
	(mL L <sup>-1</sup> )	(mL L <sup>-1</sup> d <sup>-1</sup> )	
hpt	1506.04 +/- 32.08	870.94 +/- 18.54	1409.07 +/- 46.84
19-9	1792.61 +/- 20.41	1024.34 +/- 11.66	1504.35 +/- 46.42
% improvement	16%	15%	6%

Lauren Magnusson

# Accomplishments and Progress : Increased Xylan Consumption by 22% in pH-controlled Bioreactor

- The 19-9 evolved strain utilized **22%** of the xylan, consistent with the increases in both rate (15%) and total (16%) H<sub>2</sub> production.
- Strain 19-9 displayed a lag in H<sub>2</sub> production which can be improved via further adaptation.
- Both the control ( $\Delta hpt$ ) and 19-9 mutants were derived from *C. thermocellum* DSM 1313 which can be manipulated genetically. The benchmark rate (1 L/L-d) was obtained from *C. thermocellum* ATCC 27405 which lacks a genetic system.

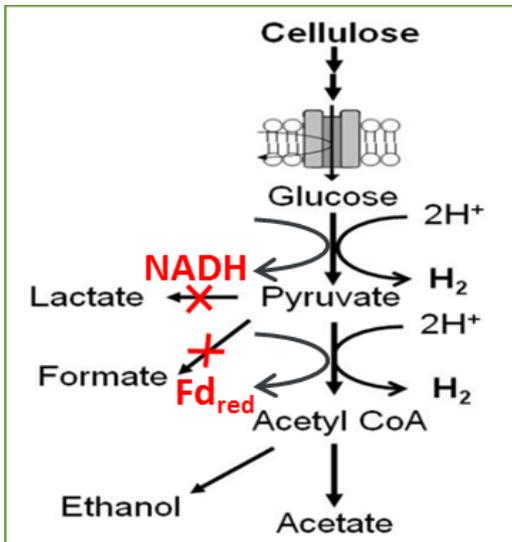

**Results demonstrated bacteria's capacity to utilize xylan, which makes further improvement promising.**

# Approach

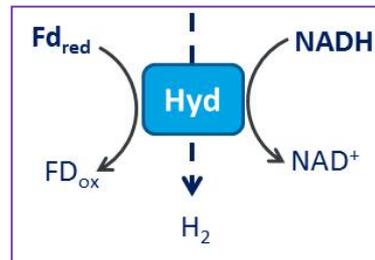

## Task 3: Generate Metabolic Pathway Mutants

**Approach:** Redirect metabolic pathways to improve H<sub>2</sub> molar yield via developing genetic methods.

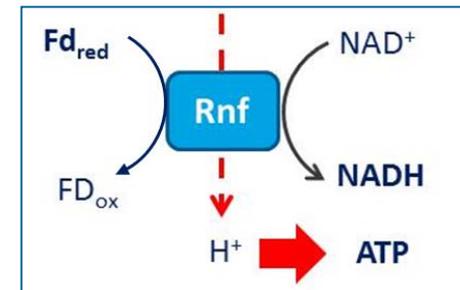

- $\Delta pfl$ : Blocking formate carbon-competing pathway led to **57% increase** in rate of H<sub>2</sub> production (2016 AMR accomplishment).
- $\Delta rnf$ : Manipulating electron-competing pathway led to **35% increase** in total H<sub>2</sub> production (2017 AMR accomplishment).

### Hydrogenase

### Transhydrogenase

<sup>13</sup>C-based metabolic flux analysis could probe metabolic changes responsible for increased H<sub>2</sub> production and guide genetic engineering.

#### FY19 Q2 Milestone

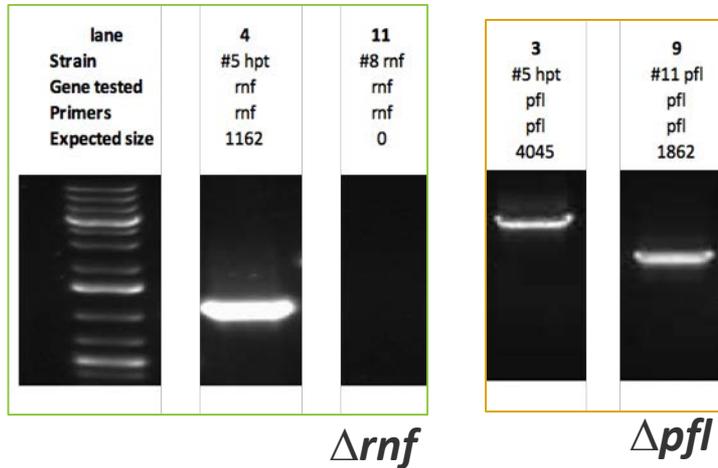

Compare growth patterns of the wild-type and mutant strains lacking either the carbon (lactate, formate) competing pathway or deficient in electron inter-conversion (ferredoxin to NADH) by growing them in two different substrates, glucose and cellobiose of different energetics. The outcome will reveal how microbes manage carbon and electron flow toward increasing H<sub>2</sub> production. (NREL).

3/2019

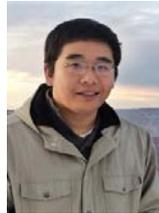

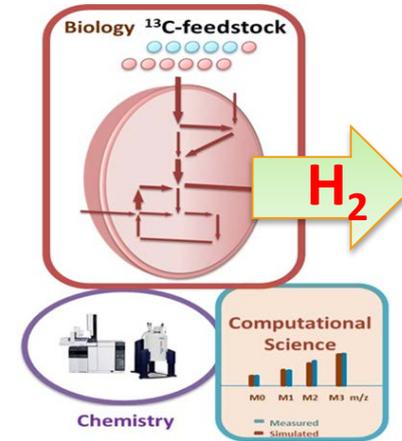

Complete

# Task 3 Accomplishments and Progress: High-throughput Phenotyping Analysis on H<sub>2</sub> Production Mutants

Genotype

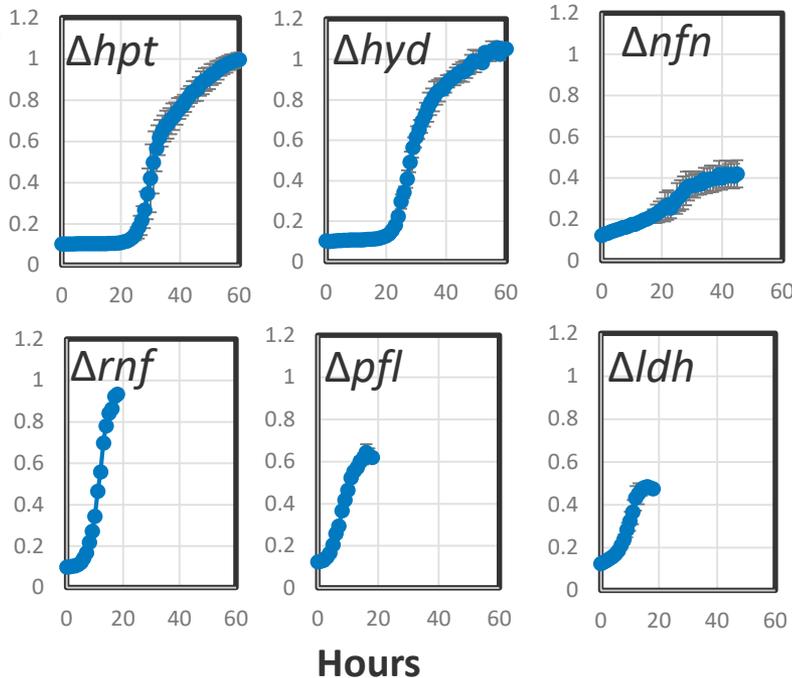

Fluxomic Phenotype

Wei Xiong

Growth Phenotype

- **Goal:** Unravel metabolic changes responsible for increased H<sub>2</sub> production via <sup>13</sup>C-metabolic flux and growth analysis, using high-throughput GC-MS and data automation pipeline
- **Progress: (1).** Mapped the <sup>13</sup>C-flux of  $\Delta hpt$  as the baseline; **(2).** Analyzed the growth phenotype of H<sub>2</sub> production mutants.

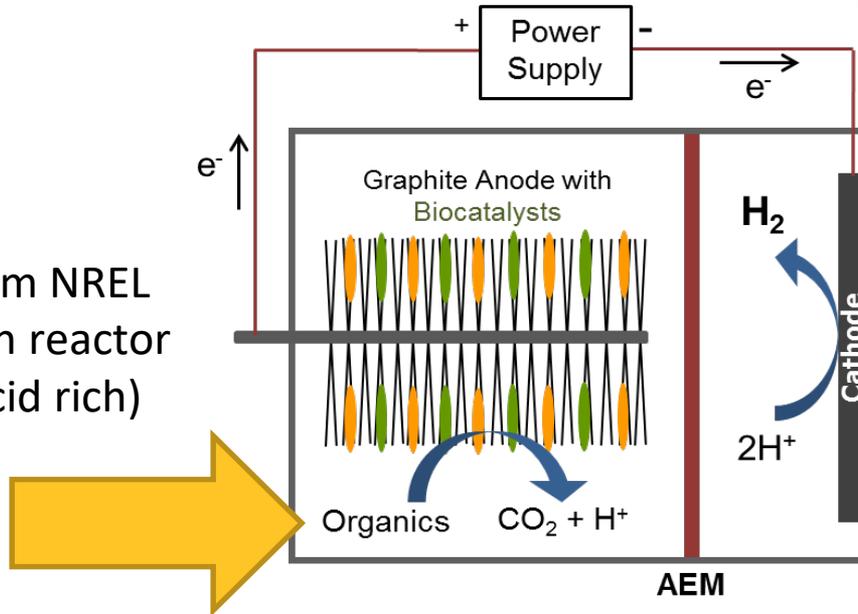

# Approach

## Task 4: Electrochemically Assisted Microbial Fermentation

### Microbial Electrolysis Cell (MEC) — Conversion of Organic Waste to Hydrogen Gas

Effluent from NREL fermentation reactor (Organic acid rich)

**Goal:** Achieving high rate of H<sub>2</sub> production with non-Pt based cathode using NREL fermentation effluent.

Bruce Logan

	Milestones (PSU)	Completion Date	Status
FY19	Evaluation of alkaline pH cathode catalysts and select new alkaline-optimized anion exchange membranes. Using a thinner cathode chamber and optimizing hydroxide ions crossover should improve overall performance by 30% (FY18 Q4; PSU*).	*1/2019 – Q4 of Penn State	Complete

# Accomplishments and Progress : Alkaline Cathode Catalyst and Membrane Resistance

**Goal:** determine if alkaline pH could improve H<sub>2</sub> production

- Use activated carbon Ni (AC-Ni) cathodes with 8.8 mg/cm<sup>2</sup> Ni salt loading.

2 g/L acetate	H <sub>2</sub> Production
pH 7	0.31± 0.02 L/L-d
pH 12	0.4 ± 0.02L/L-d

← **31% increase**

**Goal:** determine if anion-exchange membrane is the limiting factor

- Penn State has developed the “Electrode Potential Slope (EPS) to quantify internal resistance of various components including membrane.

Resistance	mΩ m <sup>2</sup>
Total	120
Felt Anode	71 ± 5
Solution	25
Cathode	18 ± 2
<b>Membrane</b>	<b>6 ± 5</b>

**Conclusion:** With its low resistance, membrane is NOT a limiting factor, and will not test/select other membranes per the milestone.

# Accomplishment:

## Achieve Stable Hydrogen Production of $>2$ L-H<sub>2</sub>/L-d Over 90 Day Period

**New MEC design:** Reduce number of brush anodes from 7 to 1 to “fill chamber.”

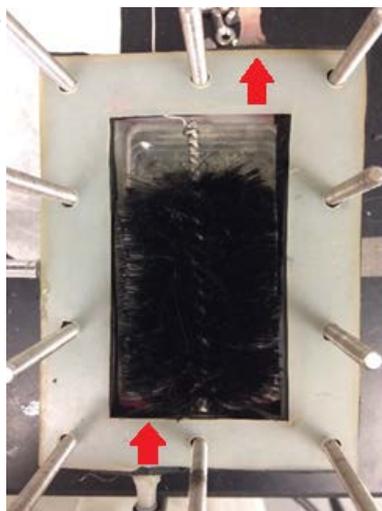

Anode: 1 brush anode (4.5cm diameter)

Cathode: 2 stainless steel wool cathodes

Electrolytes: both recirculated

**Hydrogen production** Average (90 d)= 2.62 L-H<sub>2</sub>/L-d;  
Maximum = 3.76 L-H<sub>2</sub>/L-d

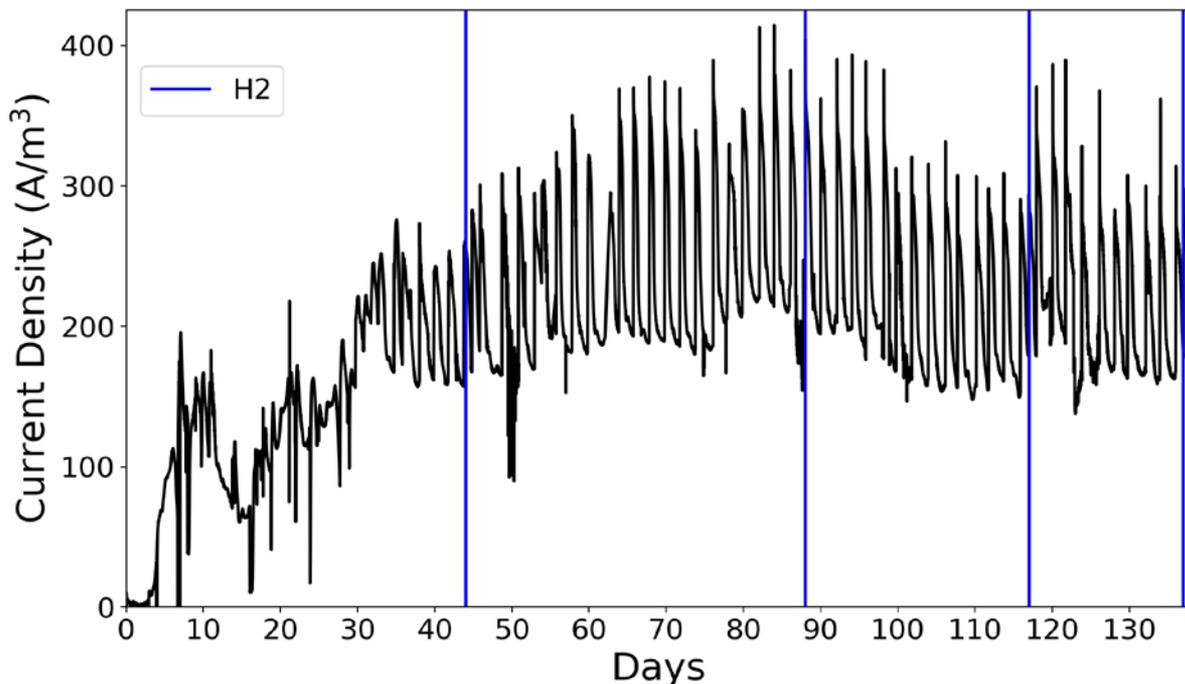

**Current density:** Average (138 d) = 197 A/m<sup>3</sup>  
Maximum = 414 A/m<sup>3</sup>

H<sub>2</sub> production average rate not yet increased by 30% over previous levels, but maximum rate was, and reactor stability was greatly improved

### Future directions:

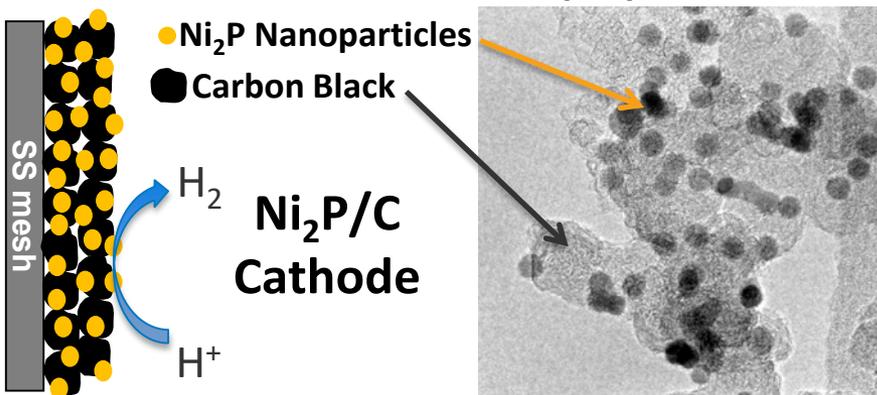

Increase anode brush diameter to 5.5 cm to completely fill the anode chamber

Student)

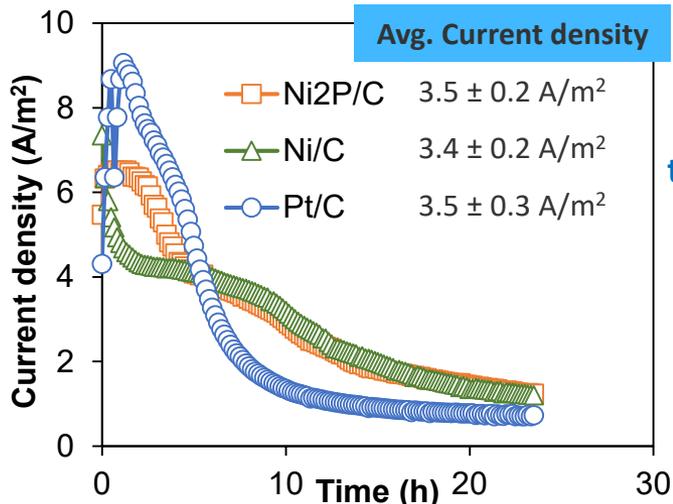

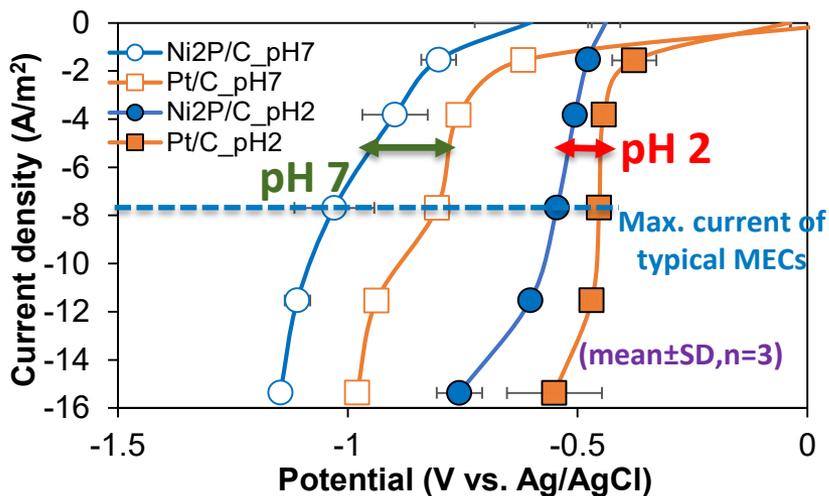

# Task 4 Accomplishments and Progress: Cathode Chamber Optimization: Replace Pt with alternative material

Nickel phosphide ( $\text{Ni}_2\text{P}$ ) nanoparticles on carbon black (CB)

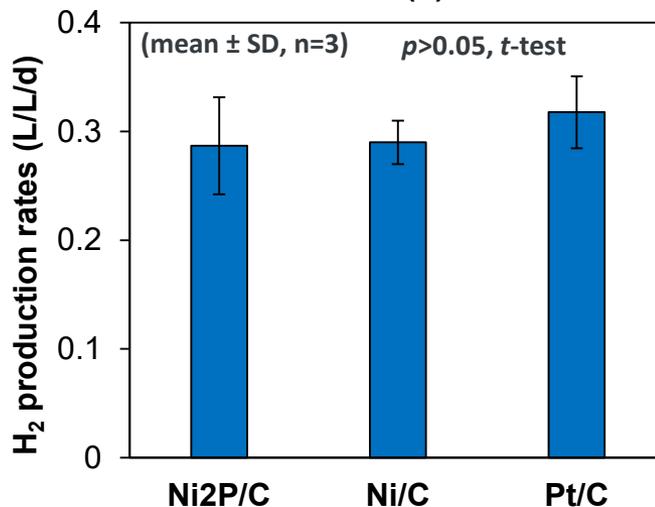

How does  $\text{Ni}_2\text{P}$  compare to Pt at pH=7 (vs pH=2) needed for MECs? (Abiotic electrochemical tests.)

Pt/C works better at pH=7 (but also true at pH=2)

MEC tests: How does  $\text{Ni}_2\text{P}$  compare to Ni or Pt over a 24 h cycle?

Result: Initially  $\text{Ni}_2\text{P} > \text{Ni}$  (but not as good as Pt)

MEC tests: Final results in  $\text{H}_2$  produced over a 24 h cycle?

Result: Insignificant different between the materials in averaged  $\text{H}_2$  production ( $p > 0.05$ )

Conclusion:  $\text{Ni}_2\text{P}/\text{C}$  cathode produced  $0.29 \pm 0.04 \text{ L-H}_2/\text{L-d}$ , comparable to a Pt cathode

Kyoung-Yeol Kim

# Accomplishments and Progress: Responses to Previous Year Reviewers' Comments

This project was presented as a poster but was not reviewed during the 2018 AMR

# Collaboration and Coordination

- **Task 1 (Bioreactor)**

Drs. Ali Mohagheghi and Melvin Tucker, National Bioenergy Center at NREL: provide DMR pretreated corn stover and their characterizations - leveraging DOE BETO funding.

- **Task 2 (Ionic Liquid) – discontinued in FY17**

Drs. Steve Singer (LBNL) and Kent Sales (SNL): conducted biomass pretreatment using ionic liquid as a complementary pretreatment approach to lower feedstock cost.

- **Task 3 (Genetic Methods)**

Dr. James Liao of UCLA in pathway engineering of *C. thermocellum* – leveraging DOE Office of Science funding.

- **Task 4 (MEC)**

Dr. Bruce Logan at Penn State University: microbial electrolysis cells to improve H<sub>2</sub> molar yield.

# Remaining Challenges and Barriers

## Task 1. Bioreactor Performance

- High solid-substrate loading (175 g/L) is needed to lower H<sub>2</sub> selling price, which might present a challenge to ensure sufficient mixing.
  - This challenge will be addressed by research in a separate project BioHydrogen Consortium, carried out by Lawrence Berkeley National Lab.

## Task 2. Fermentation of Pretreated Biomass using Ionic Liquid (LBNL/SNL)

- This task was closed out in FY17/Q1.

## Task 3. Generate Metabolic Pathway Mutant in *C. thermocellum*

- Improve the rate of xylan utilization in engineered strain to improve biomass utilization – addressed by research in a separate project “BioHydrogen Consortium”
  - Continue with adapted evolution strategy feeding xylose/xylan and select fast grower in xylan.
  - Targeted insertion of foreign genes to overcome the rate-limiting step(s) of xylan utilization.

## Task 4. Electrochemically Assisted Microbial Fermentation of Acetate (PSU)

- The Penn State subcontract ended in January 17<sup>th</sup>, 2019.

# Proposed Future Work: project is scheduled to close out in FY19/Q4

## Task 1 (NREL)

- Subject 19-9 strain to laboratory adapted evolution by continuously evolving it in avicel (earlier evolution using cellobiose) and xylan and test H<sub>2</sub> production in bioreactors.

## Task 2 (LBNL/SNL)

- None. Task 2 was discontinued in FY17/Q1.

## Task 3 (NREL)

- Adapt the various *C. thermocellum* competing-pathway mutants to grow in cellobiose for comparison of carbon flux channeling through the different metabolic pathways leading to increased H<sub>2</sub> production. The outcome will guide metabolic engineering strategies to further improve H<sub>2</sub> production (FY19 Q3 Milestone).

## Task 4 (Penn State):

- None. The Penn State subcontract ended on January 17<sup>th</sup>, 2019.

**Closeout Report.** A project closeout report will be submitted to DOE in FY19/Q4, documenting progress in the performance period of FY16-FY19 (FY19 Q4 Milestone).

# Technology Transfer Activities

## Technology-to-market or technology transfer plan or strategy

- Air Product and Chemicals, Inc.
  - Main interest in H<sub>2</sub> from biomass can be low carbon or even potentially carbon neutral; have funded the Logan lab in the past for work on MECs and RED for H<sub>2</sub> production from wastewaters
  - Large-scale process of greatest interest, but currently there are no larger reactors.
  - Cost needs to be near to, or lower than, making H<sub>2</sub> from alternative sources (natural gas).

## Plans for future funding

- Pursue opportunities to collaborate with other national Labs and industries for potential future funding support.
- Network with biofuels industry to expand the use of H<sub>2</sub>.
- Advocate the advantages of “green” H<sub>2</sub> rather than fossil-fuel derived H<sub>2</sub>

## Patents, licensing

- A Record of Invention (ROI-14-70) is filed for developing the proprietary genetic tools tailored for *C. thermocellum*.
- A second ROI-15-42 has been filed for generating xylose-metabolizing strain, leading to enhanced biomass utilization.

# Summary

## Task 1

- Using a laboratory-evolved strain we observed a **15%** increase in rate of H<sub>2</sub> production and **16%** in total H<sub>2</sub> production by co-fermenting both cellulose and xylan, benchmarking the progress.
- The evolved strain utilized **22%** more xylan, which accounts for the above increases.
- The outcomes lower the feedstock cost by converting more biomass sugars to H<sub>2</sub>.

**Task 2:** Closed out in FY17/Q1, not meeting GNG.

## Task 3

- The genotype of the various mutants were verified via PCR.
- Using a 24-well plate Microplate Reader, we performed semi high-throughput growth of the various *C. thermocellum* mutants in cellobiose which will be used for <sup>13</sup>C-metabolic flux analysis.

## Task 4

- Alkaline pH improved H<sub>2</sub> production by 31%.
- Achieve stable H<sub>2</sub> production of >2.6 L-H<sub>2</sub>/L-d over 90 day period by increasing anode brush size.
- Anion exchange membrane is not a rate-limiting step in H<sub>2</sub> production.
- Ni<sub>2</sub>P/C cathode produced 0.29±0.04 L-H<sub>2</sub>/L-d, comparable to a Pt cathode.
